#### Abstract

In [8] Dumont and Randrianarivony have given several combinatorial interpretations for the coefficients of the Euler-Seidel matrix associated to $n!$. In this paper we consider a $q$ analogue of their results, which leads to the discovery of a new mahonian statistic "maf" on the symmetric group. We then give new proofs and generalizations of some results of Gessel and Reutenauer [12] and Wachs [17].

Keywords: mahonian statistics, permutations, $q$-derangement numbers, Seidel matrices

## 1. Introduction

Euler (see [8]) considered the difference table $\left(d_{n}^{k}\right)_{0 \leq k \leq n}$, where the generic coefficients $d_{n}^{k}$ are defined by

$$
\begin{equation*}
d_{n}^{n}=n!\quad \text { and } \quad d_{n}^{k}=d_{n}^{k+1}-d_{n-1}^{k} \quad(1 \leq k \leq n-1) \tag{1.1}
\end{equation*}
$$

Let $a_{n}^{k}=d_{n+k}^{k}(n, k \geq 0)$. Then the above relations can be written as

$$
a_{0}^{k}=k!\quad \text { and } \quad a_{n}^{k}=a_{n}^{k-1}+a_{n+1}^{k-1} \quad(n, k \geq 0)
$$

The matrix $\left(a_{n}^{k}\right)_{n, k \geq 0}$ is also called the Seidel matrix associated to the sequence $a_{n}^{0}$ in the literature (see $[7,9]$ ). The first terms of these matrices are as follows:
$\left.\begin{array}{c|cccccccc|cccccc}n \backslash k & 0 & 1 & 2 & 3 & 4 & 5 & & & & k \backslash n & 0 & 1 & 2 & 3 \\ \hline\end{array}\right)$

Iterating the difference equation (1.1) we derive

$$
\begin{equation*}
a_{n}^{0}=d_{n}^{0}=n!\left(1-\frac{1}{1!}+\frac{1}{2!}-\cdots+(-1)^{n} \frac{1}{n!}\right), \tag{1.2}
\end{equation*}
$$

which is the classical derangement number $d_{n}$, that is, the number of derangements on $\{1,2, \cdots, n\}$ (cf. [16, p. 67]).

In several recent papers $[4,6,12,17]$, the $q$-maj counting of the derangements on $\{1,2, \cdots, n\}$ has been studied. Consider the $q$-derangement numbers $d_{n}(q)$ defined by

$$
\begin{equation*}
d_{n}(q)=\sum_{\sigma \in \mathcal{D}_{n}} q^{\text {maj } \sigma} \tag{1.3}
\end{equation*}
$$

where $\mathcal{D}_{n}$ is the set of all derangements on $\{1,2, \cdots, n\}$. Then the following $q$-analogue of equation (1.2) has been obtained:

$$
\begin{equation*}
d_{n}(q)=[n]_{q}!\sum_{i=0}^{n}(-1)^{i} \frac{q^{\binom{i}{2}}}{[i]_{q}!} \quad(n \geq 1) \tag{1.4}
\end{equation*}
$$

Here, $[n]_{q}=1+q+\cdots+q^{n-1}$ is the $q$-analogue of the nonnegative integer $n$ and $[n]_{q}!=$ $[1]_{q}[2]_{q} \cdots[n]_{q}$ is the $q$-analogue of $n!$.

In this paper, we shall put the $q$-derangement numbers in the context of a Seidel matrix as Dumont and Randrianarivony [8] did for the ordinary derangement numbers. To this end, in section 2 we introduce the notion of $q$-Seidel matrix. In section 3 we define a new statistic "maf" on permutations and then prove bijectively that this is a mahonian statistic. In section 4 we consider the $q$-Seidel matrix associated to the $q$ derangement numbers and give combinatorial interpretations for all of the coefficients in this matrix in terms of the new statistic "maf". As a consequence we get a new proof of a formula of Gessel and Reutenauer [12] and of Wachs [17]. Finally we close this paper with some remarks and open questions.

We will need the following notations and results of $q$-calculus (see [11]). The $q$ binomial coefficients are defined by

$$
\binom{n}{k}_{q}=\frac{[n]_{q}!}{[k]_{q}![n-k]_{q}!} \quad(n \geq k \geq 0) .
$$

Define also $(t ; q)_{n}=(1-t)(1-q t) \cdots\left(1-q^{n-1} t\right)$ and $(t ; q)_{\infty}=\lim _{n \rightarrow \infty}(t ; q)_{n}$. Then the two $q$-analogues of the exponential series $e^{t}=\sum_{n \geq 0} t^{n} / n!$ are defined by

$$
\begin{align*}
e_{q}(t) & =\sum_{n \geq 0} \frac{t^{n}}{[n]_{q}!}=\frac{1}{((1-q) t ; q)_{\infty}},  \tag{1.5}\\
E_{q}(t) & =\sum_{n \geq 0} \frac{q^{\left(\frac{n}{(n)} t^{n}\right.}}{[n]_{q}!}=(-(1-q) t ; q)_{\infty} \tag{1.6}
\end{align*}
$$

Notice that $e_{q}(t) \cdot E_{q}(-t)=1$.

## 2. $q$-Seidel matrices

Let us introduce the following generalization of Seidel matrix.
Definition 1. Given a sequence $\left(a_{n}(x, q)\right)(n \geq 0)$ of elements in a commutative ring, we call the $q$-Seidel matrix asssociated to $\left(a_{n}(x, q)\right)$ the double sequence $\left(a_{n}^{k}(x, q)\right)$ ( $n \geq 0, k \geq 0$ ) given by the recurrence

$$
\begin{cases}a_{n}^{0}(x, q)=a_{n}(x, q), & (n \geq 0)  \tag{2.7}\\ a_{n}^{k}(x, q)=x q^{n} a_{n}^{k-1}(x, q)+a_{n+1}^{k-1}(x, q) . & (k \geq 1, n \geq 0)\end{cases}
$$

Moreover $\left(a_{n}^{0}(x, q)\right)$ is called the initial sequence and $\left(a_{0}^{n}(x, q)\right)$ the final sequence of the $q$-Seidel matrix.

Lemma 1. We have

$$
\begin{equation*}
a_{n}^{k}(x, q)=\sum_{i=0}^{k}\left(x q^{n}\right)^{k-i}\binom{k}{i}_{q} a_{n+i}^{0}(x, q) . \tag{2.8}
\end{equation*}
$$

Proof: Recall that

$$
\binom{n}{k}_{q}=q^{n-1}\binom{n-1}{k-1}_{q}+\binom{n-1}{k}_{q} .
$$

We proceed by recurrence on $k$. Clearly (2.8) is valid for $k=1$. Suppose (2.8) is true for $k-1$. We then have

$$
\begin{aligned}
a_{n}^{k}(x, q)= & \sum_{i=0}^{k-1}\binom{k-1}{i}_{q}\left(\left(x q^{n}\right)^{k-i} a_{n+i}^{0}(x, q)+\left(x q^{n+1}\right)^{k-1-i} a_{n+1+i}^{0}(x, q)\right) \\
= & \left(x q^{n}\right)^{k} a_{n}^{0}(x, q)+\sum_{i=1}^{k-1}\left(x q^{n}\right)^{k-i}\binom{k-1}{i}_{q} a_{n+i}^{0}(x, q) \\
& \quad+\sum_{i=0}^{k-2}\left(x q^{n+1}\right)^{k-1-i}\binom{k-1}{i}_{q} a_{n+1+i}^{0}(x, q)+a_{n+k}^{0}(x, q) \\
= & \left(x q^{n}\right)^{k} a_{n}^{0}(x, q)+\sum_{i=1}^{k-1}\left(x q^{n}\right)^{k-i}\binom{k}{i}_{q} a_{n+i}^{0}(x, q)+a_{n+k}^{0}(x, q) .
\end{aligned}
$$

Thus completes the proof.

In particular we pass from the initial sequence to the final sequence and conversely by the Gauss inversion formula [2, p. 96]:

$$
\begin{align*}
& a_{0}^{n}(x, q)=\sum_{i=0}^{n} x^{n-i}\binom{n}{i}_{q} a_{i}^{0}(x, q),  \tag{2.9}\\
& a_{n}^{0}(x, q)=\sum_{i=0}^{n}(-x)^{n-i} q^{\binom{n-i}{2}}\binom{n}{i}_{q} a_{0}^{i}(x, q) . \tag{2.10}
\end{align*}
$$

Define the generating functions as follows:

$$
a(t)=\sum_{n \geq 0} a_{n}^{0}(x, q) t^{n}, \quad \bar{a}(t)=\sum_{n \geq 0} a_{0}^{n}(x, q) t^{n}
$$

and

$$
A(t)=\sum_{n \geq 0} a_{n}^{0}(x, q) \frac{t^{n}}{[n]_{q}!}, \quad \bar{A}(t)=\sum_{n \geq 0} a_{0}^{n}(x, q) \frac{t^{n}}{[n]_{q}!} .
$$

Proposition 2. The generating functions of the initial and final sequences are related by the following equations:

$$
\begin{align*}
\bar{a}(t) & =\sum_{n \geq 0} a_{n}^{0}(x, q) \frac{t^{n}}{(x t ; q)_{n+1}}  \tag{2.11}\\
\bar{A}(t) & =e_{q}(x t) A(t) \tag{2.12}
\end{align*}
$$

Proof: Note that

$$
\frac{1}{(t ; q)_{n+1}}=\sum_{k=0}^{\infty}\binom{n+k}{k}_{q} t^{k} .
$$

Hence

$$
\begin{aligned}
\sum_{n \geq 0} a_{n}^{0}(x, q) \frac{t^{n}}{(x t ; q)_{n+1}} & =\sum_{n, k \geq 0}\binom{n+k}{k}_{q} a_{n}^{0}(x, q) x^{k} t^{n+k} \\
& =\sum_{m \geq 0} t^{m} \sum_{n=0}^{m}\binom{m}{n}_{q} x^{m-n} a_{n}^{0}(x, q) \\
& =\sum_{m \geq 0} a_{0}^{m}(x, q) t^{m}
\end{aligned}
$$

By (1.5) we have

$$
\begin{aligned}
e_{q}(x t) A(t) & =\sum_{i, j \geq 0} \frac{a_{i}^{0}(x, q) t^{i}}{[i]_{q}!} \cdot \frac{x^{j} t^{j}}{[j]_{q}!} \\
& =\sum_{i, j \geq 0}\binom{i+j}{i}_{q} a_{i}^{0}(x, q) x^{j} \frac{t^{i+j}}{[i+j]_{q}!} \\
& =\sum_{n \geq 0}\left(\sum_{i=0}^{n} x^{n-i}\binom{n}{i}_{q} a_{i}^{0}(x, q)\right) \frac{t^{n}}{[n]_{q}!},
\end{aligned}
$$

which completes the proof of (2.12) in view of (2.9).

Remark: If $x=q=1$ we get the classical formulas [7,9]:

$$
\bar{a}(t)=\frac{1}{1-t} a\left(\frac{t}{1-t}\right) \quad \text { and } \quad \bar{A}(t)=e^{t} A(t)
$$

If $x=0$ we have $\bar{A}(t)=A(t)$.

## 3. A new mahonian statistic "maf"

Let $S_{n}$ be the set of permutations on $[n]=\{1,2, \ldots, n\}$. Recall that $i \in[n]$ is a fixed point of $\sigma \in S_{n}$ if $\sigma(i)=i$. Let fix $\sigma$ denote the number of fixed points of $\sigma$. The permutation $\sigma$ has a descent at $i \in\{1,2, \ldots, n-1\}$ if $\sigma(i)>\sigma(i+1)$ and we call $i$ the descent place of $\sigma$. The major index of $\sigma$, denoted maj $\sigma$, is the sum of all the descent places of $\sigma$. Let $\operatorname{FIX}(\sigma)=\{i \mid \sigma(i)=i\}$ be the set of all fixed points of $\sigma$ and $\tilde{\sigma}$ the restriction of $\sigma$ to $\{1,2, \ldots, n\} \backslash \operatorname{FIX}(\sigma)$.

Definition 2. If $\sigma \in S_{n}$ with $\operatorname{FIX}(\sigma)=\left\{i_{1}, i_{2}, \ldots, i_{l}\right\}$, then the statistic "maf" is defined by

$$
\operatorname{maf} \sigma=\sum_{j=1}^{l}\left(i_{j}-j\right)+\operatorname{maj} \tilde{\sigma}
$$

Example 1. Let $\sigma=321659487$. Then $\operatorname{FIX}(\sigma)=\{2,5,8\}$ and $\tilde{\sigma}=316947$. Hence fix $\sigma=3$, maj $\sigma=1+2+4+6+8=21$ and $\operatorname{maf} \sigma=(2-1)+(5-2)+(8-3)+(1+$ 4) $=14$.

We now show that the bistatistics (fix, maf) and (fix, maj) are equidistributed on the symmetric group $S_{n}$ (Corollary 7). In particular, this shows that maf is a Mahonian statistic.

Let $\sigma=x_{1} x_{2} \ldots x_{n} \in S_{n}$. For convenience we put $x_{0}=-\infty$ and $x_{n+1}=+\infty$. For $0 \leq i \leq n$, a pair $(i, i+1)$ of positions is the $j$-th slot of $\sigma$ provided that $x_{i} \neq i$, i.e., $i$ is not a fixed point of $\sigma$ and that $\sigma$ has $i-j$ fixed points $f$ such that $f<i$. Clearly we can insert a fixed point into the $j$-th slot to obtain the permutation

$$
\begin{equation*}
(\sigma, j)=x_{1}^{\prime} x_{2}^{\prime} \ldots x_{i}^{\prime}(i+1) x_{i+1}^{\prime} \ldots x_{n}^{\prime} \tag{3.13}
\end{equation*}
$$

where $x^{\prime}=x$ if $x \leq i$ and $x^{\prime}=x+1$ if $x>i$.
More generally, if $\sigma$ is a derangement in $S_{n}$ and $\left(i_{1}, i_{2}, \ldots, i_{m}\right)$ a sequence of integers such that $0 \leq i_{1} \leq i_{2} \leq \cdots \leq i_{m} \leq n$, we can insert $m$ fixed points into the derangement $\sigma$ successively, finally obtaining

$$
\left(\sigma, i_{1}, \ldots, i_{m}\right)=\left(\left(\sigma, i_{1}, \ldots, i_{m-1}\right), i_{m}\right) .
$$

Note that the fixed points of this last permutation are $i_{1}+1, i_{2}+2, \ldots, i_{m}+m$.
Example 2. Let $\sigma=2143$ and $\left(i_{1}, i_{2}, \ldots, i_{m}\right)=(0,1,1,4)$. Then we have $(\sigma, 0)=$ $13254,(\sigma, 0,1)=143265,(\sigma, 0,1,1)=1534276$ and $(\sigma, 0,1,1,4)=15342768$.

We can of course undertake the reverse operation. That is, if a permutation $\sigma$ in $S_{m+n}$ has $m$ fixed points we can find a unique derangement $\mathrm{dp}(\sigma) \in S_{n}$, called (following Wachs [17]) the derangement part of $\sigma$, and a unique sequence of integers $i_{1} \leq \cdots \leq i_{m}$, which we call the fixed point sequence of $\sigma$, such that

$$
\sigma=\left(\operatorname{dp}(\sigma), i_{1}, \ldots, i_{m}\right)
$$

It is easy to see that

$$
\begin{equation*}
\operatorname{maf} \sigma=\operatorname{majdp}(\sigma)+i_{1}+\cdots+i_{m} \tag{3.14}
\end{equation*}
$$

Consider a permutation $\sigma$ with $n$ slots. The $j$-th slot $(i, i+1)$ of $\sigma$ is said to be green if $\operatorname{des}(\sigma, j)=\operatorname{des} \sigma$, red if $\operatorname{des}(\sigma, j)=\operatorname{des} \sigma+1$. We assign values to the green slots of $\sigma$ from right to left, from 0 to $g$, and to the red slots from left to right, from $g+1$ to $n$. Denote the value of the $j$-th slot by $g_{j}$. (When we refer to the "largest" slot, we will mean largest in terms of $j$.)

Example 3. Let $\sigma=2143$. Then $(\sigma, 0)=13254,(\sigma, 1)=32154,(\sigma, 2)=21354$, $(\sigma, 3)=21543,(\sigma, 4)=21435$. Hence slots 0,2 and 4 are green, while 1 and 3 are red. Therefore

$$
\begin{equation*}
\left(g_{0}, \ldots, g_{n}\right)=(2,3,1,4,0) \tag{3.15}
\end{equation*}
$$

It is easy to see that every slot is either green or red. In fact, one can see that $(i, i+1)$ is green if either $x_{i+1}<x_{i} \leq i$, or $i<x_{i+1}<x_{i}$, or $x_{i} \leq i<x_{i+1}$. So $(i, i+1)$ is red if either $x_{i+1} \leq i<x_{i}$, or $i<x_{i}<x_{i+1}$ or $x_{i}<x_{i+1} \leq i$. (Expressed in terms of cyclic intervals (cf. [13]), slot $(i, i+1)$ is green if $i+1 \in \rrbracket x_{i}, x_{i+1} \rrbracket$.)

Denote by $d_{j}$ the number of descents of $(\sigma, j)$ that lie to the right of $x_{i}^{\prime}$ in (3.13).
Lemma 3. Let $\sigma$ be a permutation in $S_{n}$. If the $j$-th slot $(i, i+1)$ is green then $\operatorname{maj}(\sigma, j)-\operatorname{maj} \sigma=d_{j}$, if $(i, i+1)$ is red then $\operatorname{maj}(\sigma, j)-$ maj $\sigma=d_{j}+i$.
Proof: Let $(i, i+1)$ be a green slot. Since no new descents are formed by inserting a fixed point into the $j$-th slot of $\sigma, \operatorname{maj}(\sigma, j)-$ maj $\sigma$ equals the number of descents of $\sigma$ that are displaced to the right when this fixed point is inserted. This number equals $d_{j}$. The case in which $(i, i+1)$ is red is dealt with similarly.

Remark: If $\sigma$ is a derangement in $S_{n}$, the $j$-th slot of $\sigma$ is just $(j, j+1)$ for $0 \leq j \leq n$.
Lemma 4. If $\sigma$ is a derangement in $S_{n}$, then

$$
\operatorname{maj}(\sigma, j)=\operatorname{maj} \sigma+g_{j} \quad \text { for } \quad 0 \leq j \leq n
$$

Proof: Let $i$ and $j$ be slots. It follows from Lemma 3 that if $i$ and $j$ are both green and $i<j$ then $\operatorname{maj}(\sigma, i) \geq \operatorname{maj}(\sigma, j)$, while if $i$ and $j$ are both red and $i<j$ then $\operatorname{maj}(\sigma, i) \leq$ $\operatorname{maj}(\sigma, j)$. Therefore 0 is the green slot of $\sigma$ of highest value, and if $i$ is red and $j$ is green we have maj $(\sigma, i) \geq \operatorname{maj}(\sigma, j)$. This is because for any red slot $i$ we have $\operatorname{maj}(\sigma, i) \geq \operatorname{maj}(\sigma, 0)$ by Lemma 3. Hence, if $m$ is the largest red slot of $\sigma$, i.e., $g_{m}=n$, for any two slots $i$ and $j$ with $g_{i}<g_{j}$ we have

$$
\operatorname{maj} \sigma \leq \operatorname{maj}(\sigma, i) \leq \operatorname{maj}(\sigma, j) \leq \operatorname{maj}(\sigma, m)
$$

It therefore suffices to show that

$$
\operatorname{maj}(\sigma, m)=\operatorname{maj} \sigma+n
$$

Now, consider a green slot $(i, i+1)$. If $i+1$ is a non-excedance place, i.e., $x_{i+1} \leq i+1$, then, as $\sigma$ is a derangment, $x_{i+1} \leq i$. Hence $x_{i+1}<x_{i} \leq i$. Thus $i$ is a non-excedance place. Since $n$ is a non-excedance place and $m+1, m+2, \ldots, n$ are green slots, we have

$$
m+1>x_{m+1}>\cdots>x_{n} .
$$

As the slot $m$ is red, either $m$ is a non-excedance place and $m$ is a non-descent or $m$ is an excedance place and $m$ is a descent. In each case, inserting a fixed point into the $m$-th slot introduces a new descent for $i=m+1$ and moves $n-(m+1)$ descents one place further to the right. Hence

$$
\operatorname{maj}(\sigma, m)=\operatorname{maj} \sigma+(m+1)+(n-m-1)=\operatorname{maj} \sigma+n
$$

as required.

Remark: Suppose that $\sigma$ is a derangement in $S_{n}$ and $0 \leq i \leq n$. It follows from Lemmas 3 and 4 that $d_{i}=g_{i}$ if $i$ is green and $d_{i}=g_{i}-i$ if $i$ is red. If $i$ is green then

$$
\operatorname{maj}(\sigma, i, i)=\operatorname{maj}(\sigma, i)+g_{i} .
$$

Hence, if $j \leq i$, it follows from Lemma 4 that

$$
\operatorname{maj}(\boldsymbol{\sigma}, j, i)=\operatorname{maj}(\boldsymbol{\sigma}, i)+g_{j}
$$

On the other hand, if $i$ is red, then

$$
\operatorname{maj}(\sigma, i, i)=\operatorname{maj}(\sigma, i)+g_{i}-i
$$

Now one can easily see that, if $k$ is the largest green slot to the left of slot $i, g_{k}=g_{i}-i$. Hence, if $j<i$, it follows again from Lemma 4 that

$$
\operatorname{maj}(\sigma, j, i)=\operatorname{maj}(\sigma, i)+g_{j}+1
$$

We are now ready to state the key result of this section. Let $S(\sigma, m)$ denote the set of permutations in $S_{n+m}$ with derangement part $\sigma \in \mathcal{D}_{n}$. Note that

$$
S(\sigma, m)=\left\{(\boldsymbol{\sigma}, \mathbf{i}) \mid \mathbf{i}=\left(i_{1}, \ldots, i_{m}\right) \text { and } 0 \leq i_{1} \leq i_{2} \leq \cdots \leq i_{m} \leq n\right\} .
$$

Theorem 5. There is a bijection $\Psi$ on $S(\sigma, m)$ such that if $\Psi(\sigma, \mathbf{i})=(\sigma, \mathbf{j})$ then

$$
\begin{equation*}
\operatorname{maj}(\sigma, \mathbf{i})=\operatorname{maf}(\sigma, \mathbf{j}) \tag{3.16}
\end{equation*}
$$

Proof: We divide the proof into two parts.
The definition of $\Psi$. We will define such a bijection $\Psi$ by induction on $m \geq 0$.

First, $\Psi$ is the identity mapping on $S(\sigma, 0)$. Next, we define $\Psi$ on $S(\sigma, 1)$ by

$$
\Psi(\sigma, i)=\left(\sigma, g_{i}\right) .
$$

Then using equation (3.14) and Lemma 4 we see that $\Psi$ satisfies equation (3.16).
Let $m>1$ and suppose that $\Psi$ has been defined on $S(\sigma, k)$ for $0 \leq k \leq m-1$. Consider $\tau=\left(\sigma, i_{1}, \ldots, i_{m}\right)$. Suppose that the $i_{m}$-th slot of $\left(\sigma, i_{1}, \ldots, i_{m-1}\right)$ is green. Then, if

$$
\Psi\left(\sigma, i_{1}, \ldots, i_{m-1}\right)=\left(\sigma, j_{2}, \ldots, j_{m}\right)
$$

we define

$$
\Psi(\tau)=\left(\sigma, g_{i_{m}}, j_{2}, \ldots, j_{m}\right)
$$

Suppose that the $i_{m}$-th slot of $\left(\sigma, i_{1}, \ldots, i_{m-1}\right)$ is red. Then the slots $i_{1}, \ldots, i_{m}$ cannot be all the same. Let $k$ be the smallest positive integer such that $i_{m-k}<i_{m}$. Thus $i_{m-k}<$ $i_{m-k+1}=\cdots=i_{m}$. Then, if

$$
\Psi\left(\sigma, i_{1}, \ldots, i_{m-k}\right)=\left(\sigma, j_{1}, \ldots, j_{m-k}\right),
$$

we define

$$
\Psi(\tau)=(\sigma, \underbrace{g_{i_{m}}-i_{m}, \ldots, g_{i_{m}}-i_{m}}_{k-1 \text { terms }}, j_{1}+1, \ldots, j_{m-k}+1, g_{i_{m}}) .
$$

The following lemma is easily proved by induction.
Lemma 6. Let $\tau=\left(\sigma, i_{1}, \ldots, i_{m}\right)$ and $\Psi(\tau)=\left(\sigma, j_{1}, \ldots, j_{m}\right)$.
Suppose that at least one of the slots $i_{1}, \ldots, i_{m}$ is either green or is repeated. Let $i_{l}$ be the largest such slot. If $i_{l}$ is green then $j_{1}=g_{i_{l}}$. If $i_{l}$ is red and is repeated then $j_{1}=g_{i_{l}}-i_{l}$.

If on the other hand all of the slots $i_{1}, \ldots, i_{m}$ are red and are distinct, then $j_{1}=g_{i_{1}}$.
Suppose that at least one of the slots $i_{1}, \ldots, i_{m}$ is red. If $i_{l}$ is the largest red slot then $j_{m}=g_{i l}$.

If on the other hand all of these slots are green then $j_{m}=g_{i_{1}}$.
It follows from this lemma that $j_{1}, \ldots, j_{m}$ as defined above are in ascending order.
We now show by induction on $m$ that $\Psi$ satisfies equation (3.16).
If $i_{m}$ is green, then using Lemma 4 we have

$$
\begin{aligned}
\operatorname{maj}\left(\sigma, i_{1}, \ldots, i_{m}\right) & =\operatorname{maj}\left(\sigma, i_{1}, \ldots, i_{m-1}\right)+g_{i_{m}} \\
& =\operatorname{maf}\left(\sigma, j_{2}, \ldots, j_{m}\right)+g_{i_{m}} \\
& =\operatorname{maf}\left(\sigma, g_{i_{m}}, j_{2}, \ldots, j_{m}\right)
\end{aligned}
$$

If $i_{m}$ is red, let $k$ be the smallest positive integer such that $i_{m-k}<i_{m}$, then

$$
\begin{aligned}
& \operatorname{maj}\left(\sigma, i_{1}, \ldots, i_{m}\right) \\
& \quad=\operatorname{maj}\left(\sigma, i_{1}, \ldots, i_{m-k}\right)+(m-k)+(k-1)\left(g_{i_{m}}-i_{m}\right)+g_{i_{m}} \\
& =\operatorname{maf}\left(\sigma, j_{1}, \ldots, j_{m-k}\right)+(m-k)+(k-1)\left(g_{i_{m}}-i_{m}\right)+g_{i_{m}} \\
& \quad=\operatorname{maf}(\sigma, \underbrace{g_{i_{m}}-i_{m}, \ldots, g_{i_{m}}-i_{m}}_{k-1 \text { terms }}, j_{1}+1, \ldots, j_{m-k}+1, g_{i_{m}}) .
\end{aligned}
$$

This is because inserting the first fixed point $i_{m}$ into ( $\sigma, i_{1}, \ldots, i_{m-k}$ ) adds a descent and increases maj by $g_{i_{m}}+(m-k)$. Inserting each of the remaining fixed points $i_{m}$ has the same affect as inserting a fixed point into a green slot of value $g_{i_{m}}-i_{m}$.
$\Psi$ is a bijection. It remains to show that $\Psi$ is a bijection on $S(\sigma, m)$. It suffices to show that $\Psi$ is an injection.

We use induction on $m$. The result is clearly true for $m=0$ and $m=1$.
Let $\tau=\left(\sigma, i_{1}, \ldots, i_{m}\right)$ and $\Psi(\tau)=\left(\sigma, j_{1}, \ldots, j_{m}\right)$. Suppose that $\Psi(\tau)=\Psi\left(\tau^{\prime}\right)$, where $\tau^{\prime}=\left(\sigma, i_{1}^{\prime}, \ldots, i_{m}^{\prime}\right)$.

If both $i_{m}$ and $i_{m}^{\prime}$ are green or red then it is easy to show using the induction hypothesis that $\tau=\tau^{\prime}$. So suppose that $i_{m}$ is green and $i_{m}^{\prime}$ is red. Thus $j_{1}=g_{i_{m}}, j_{m}=g_{i_{m}^{\prime}}$.

Suppose that $i_{1}, \ldots, i_{m}$ are all green. Then $j_{m}=g_{i_{1}}$. Hence $i_{1}=i_{m}^{\prime}$, contradiction.
Let $i_{u}$ be the largest red slot amongst $i_{1}, \ldots, i_{m}$. Then $j_{m}=g_{i_{u}}$. Hence $i_{m}^{\prime}=i_{u}<i_{m}$.
Case 1: Suppose that one of the slots $i_{1}^{\prime}, \ldots, i_{m}^{\prime}$ is either green or is repeated. Let $i_{v}^{\prime}$ be the largest such slot. If $i_{v}^{\prime}$ is green, then

$$
\Psi\left(\tau^{\prime}\right)=\left(\sigma, g_{i_{v}^{\prime}}+(m-v), \ldots, g_{i_{m}^{\prime}}\right)
$$

Hence $j_{1}=g_{i_{m}}=g_{i_{v}^{\prime}}+(m-r)$. Since $i_{m}$ and $i_{v}^{\prime}$ are both green, this means that $i_{m} \leq$ $i_{v}^{\prime}<i_{m}^{\prime}$, contradiction.

If $i_{v}^{\prime}$ is red, then

$$
\Psi\left(\tau^{\prime}\right)=\left(\sigma, g_{i_{v}^{\prime}}-i_{v}^{\prime}+(m-v), \ldots, g_{i_{m}^{\prime}}\right)
$$

Hence $j_{1}=g_{i_{m}}=g_{i_{v}^{\prime}}-i_{v}^{\prime}+(m-r)$. But $g_{i_{v}^{\prime}}-i_{v}^{\prime}$ is the value of the largest green slot $i_{w}$ less than $i_{v}^{\prime}$. As $i_{m}$ is green this means that $i_{m} \leq i_{w}<i_{v}^{\prime} \leq i_{m}^{\prime}$, contradiction.

Case 2: Suppose that all of the slots $i_{1}^{\prime}, \ldots, i_{m}^{\prime}$ are red and distinct. Then

$$
\Psi\left(\tau^{\prime}\right)=\left(\sigma, g_{i_{1}^{\prime}}+(m-1), \ldots, i_{m}^{\prime}\right)
$$

Hence $j_{1}=g_{i_{m}}=g_{i_{1}}^{\prime}+(m-1)>g_{i-1}^{\prime}$. This is a contradiction, since $i_{m}$ is green and $i_{1}^{\prime}$ is red.

Example 4. Let $\sigma=2143$ and consider $(\sigma, 0,1,1,4) \in S(\sigma, 4)$. Then the values of the slots of $\sigma$ have been calculated in (3.15). The bijection $\Psi$ goes as follows: since slot 0 is green in $\sigma$ we have

$$
\Psi(\sigma, 0)=\left(\sigma, g_{0}\right)=(\sigma, 2)
$$

since slot 1 is red we have

$$
\Psi(\sigma, 0,1)=\left(\sigma, 2+1, g_{1}\right)=(\sigma, 3,3)
$$

again, since slot 1 is red we have

$$
\Psi(\sigma, 0,1,1)=\left(\sigma, g_{1}-1,2+1, g_{1}\right)=(\sigma, 2,3,3)
$$

Finally, since slot 4 is green we obtain

$$
\Psi(\sigma, 0,1,1,4)=\left(\sigma, g_{4}, 2,3,3\right)=(\sigma, 0,2,3,3) \in S(\sigma, 4)
$$

Let $\tau=(\sigma, 0,1,1,4)$ and $\tau^{\prime}=(\sigma, 0,2,3,3)$. Then $\tau=15342768$ and $\tau^{\prime}=13248675$. It is easy to see that maj $\tau=12$ and maf $\tau^{\prime}=12$. Hence we have checked equation (3.16).

Using theorem 5, we obtain the following result.
Corollary 7. (a) There is a bijection $\phi: S_{n} \rightarrow S_{n}$ such that for any $\sigma \in S_{n}$ we have

$$
(\mathrm{fix}, \mathrm{maf}) \boldsymbol{\sigma}=(\mathrm{fix}, \mathrm{maj}) \phi(\boldsymbol{\sigma}) .
$$

(b) The bi-statistic (fix, maf) is equidistributed with the bi-statistic (fix, maj) on the symmetric group $S_{n}$.

The following result was first proved by Wachs [17, corollary 3].
Corollary 8. Let $\sigma$ be a derangement in $S_{n}$ and $m \geq 0$. We have

$$
\sum_{\pi \in S(\sigma, m)} q^{\operatorname{maj} \pi}=q^{\operatorname{maj} \sigma}\binom{m+n}{n}_{q} .
$$

Proof: By theorem 5 we have

$$
\begin{aligned}
\sum_{\pi \in S(\sigma, m)} q^{\operatorname{maj} \pi} & =\sum_{\pi \in S(\sigma, m)} q^{\operatorname{maf} \pi} \\
& =q^{\operatorname{maj} \sigma} \sum_{0 \leq i_{1} \leq \cdots \leq i_{m} \leq n} q^{i_{1}+i_{2}+\cdots i_{m}} \\
& =q^{\operatorname{maj} \sigma}\binom{m+n}{n}_{q}
\end{aligned}
$$

The last line follows from a well-known result [1, p. 33].

## 4. $q$-derangement matrices

We first prove the following result.
Proposition 9. Let $\left(a_{n}^{k}(x, q)\right)$ be a $q$-Seidel matrix. Then the following three conditions are equivalent:

$$
\begin{align*}
& a_{n}^{0}(x, q)=[n]_{q}!\sum_{i=0}^{n}(-1)^{i} \frac{q^{\left(\frac{i}{2}\right)}}{[i]_{q}!},  \tag{4.17}\\
& a_{0}^{n}(x, q)=[n]_{q}!\left(1+\sum_{i=1}^{n} \frac{(x-1)(x-q) \cdots\left(x-q^{i-1}\right)}{[i]_{q}!}\right),  \tag{4.18}\\
& a_{0}^{n}(1, q)=[n]_{q}!\quad \text { and } \quad a_{n}^{0}(x, q) \quad \text { is independent of } x . \tag{4.19}
\end{align*}
$$

Proof: By the $q$-binomial formula [11, p.7]

$$
\sum_{n=0}^{\infty} \frac{(a ; q)_{n}}{(q ; q)_{n}} t^{n}=\frac{(a t ; q)_{\infty}}{(t ; q)_{\infty}},
$$

we have in view of (1.5) and (1.6),

$$
1+\sum_{n=1}^{\infty} \frac{(x-1)(x-q) \cdots\left(x-q^{n-1}\right)}{[n]_{q}!} t^{n}=e_{q}(x t) E_{q}(-t)
$$

Therefore the generating functions of (4.17), (4.18) and (4.19) are respectively the following:

$$
\begin{align*}
A(t) & =\sum_{n \geq 0} a_{n}^{0}(x, q) \frac{t^{n}}{[n]_{q}!}=\frac{E_{q}(-t)}{1-t},  \tag{4.20}\\
\bar{A}(t) & =\sum_{n \geq 0} a_{0}^{n}(x, q) \frac{t^{n}}{[n]_{q}!}=\frac{e_{q}(x t) E_{q}(-t)}{1-t},  \tag{4.21}\\
\left.\bar{A}(t)\right|_{x=1} & =\sum_{n \geq 0} a_{0}^{n}(1, q) \frac{t^{n}}{[n]_{q}!}=\frac{1}{1-t} . \tag{4.22}
\end{align*}
$$

So, it suffices to prove that the equivalence of (4.20), (4.21) and (4.22). Indeed,
(4.20) $\Longleftrightarrow(4.21)$ : this follows from proposition 2 ;
$(4.21) \Longrightarrow(4.22)$ : this is obvious;
(4.22) $\Longrightarrow(4.20)$ : since $A(t)$ is independent of $x$, equation (4.20) follows then from (2.12) by setting $x=1$.

Definition 3. A q-derangement matrix is the $q$-Seidel matrix satisfying any of the three conditions of proposition 8 .

If $x=1$, then $a_{0}^{n}(x, q)=[n]_{q}$ ! and the $q$-derangement matrix is as follows :

| $k \backslash n$ | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | $q$ | $q+q^{2}$ | $\binom{q+2 q^{2}+2 q^{3}}{+2 q^{4}+q^{5}+q^{6}}$ |
| 1 | 1 | $q$ | $q+q^{2}+q^{3}$ | $\left(\begin{array}{c}q+2 q^{2}+2 q^{3} \\ \left.+3 q^{2}+2 q^{5}+q^{6}\right)\end{array}\right.$ |  |
| 2 | $1+q$ | $q+2 q^{2}+q^{3}$ | $\left(\begin{array}{c}q+2 q^{2}+3 q^{3} \\ \left.+4 q^{4}+3 q^{5}+q^{6}\right)\end{array}\right.$ |  |  |
| 3 | $[3]_{q}!$ | $\left(\begin{array}{c}q+3 q^{2}+5 q^{3} \\ \left.+5 q^{4}+3 q^{5}+q^{6}\right)\end{array}\right.$ |  |  |  |
| 4 | $[4]_{q}!$ |  |  |  |  |

$$
\left(a_{n}^{k}(1, q)\right)
$$

Denote by $S_{n}^{k}$ the set of permutations on $[n+k]$ of which all the fixed points are included in $\{n+1, n+2, \ldots, n+k\}$. In particular $S_{n}^{0}$ is the set of permutations without fixed points on $[n]$ and $\mathcal{S}_{0}^{k}$ the set of all permutations on $[k]$. The following result generalizes a result of Dumont and Randrianarivony [8].
Theorem 10. The coefficients $a_{n}^{k}(x, q)(n, k \geq 0)$ in a q-derangement matrix have the following combinatorial interpretation:

$$
\begin{equation*}
a_{n}^{k}(x, q)=\sum_{\sigma \in S_{n}^{k}} x^{\mathrm{fix} \sigma} q^{\mathrm{maf} \mathrm{\sigma}} \tag{4.23}
\end{equation*}
$$

Proof: Notice that $S_{n+1}^{k-1} \subset \mathcal{S}_{n}^{k}$. Set

$$
\Delta_{n}^{k}=S_{n}^{k} \backslash S_{n+1}^{k-1}=\left\{\sigma \in S_{n}^{k} \mid \sigma(n+1)=n+1\right\}
$$

We construct a bijection $\varphi: \Delta_{n}^{k} \rightarrow S_{n}^{k-1}$ such that for all $\sigma \in \Delta_{n}^{k}$,

$$
\begin{aligned}
\operatorname{maf} \sigma & =n+\operatorname{maf}(\varphi(\sigma)) \\
\operatorname{fix} \sigma & =1+\operatorname{fix}(\varphi(\sigma))
\end{aligned}
$$

Indeed, if $\sigma \in \Delta_{n}^{k}$ we define $\varphi(\sigma)$ as the word obtained from $\sigma$ by deleting $n+1$ and reduce all the values strictly bigger than $n+1$. It is readily verified that $\varphi$ is the desired bijection. Therefore

$$
\begin{equation*}
\sum_{\sigma \in S_{n}^{k}} x^{\mathrm{fix} \sigma} q^{\mathrm{maf} \sigma}=x q^{n} \sum_{\sigma \in S_{n}^{k-1}} x^{\mathrm{fix} \sigma} q^{\mathrm{maf} \sigma}+\sum_{\sigma \in S_{n+1}^{k-1}} x^{\mathrm{fix} \sigma} q^{\mathrm{maf} \sigma} \tag{4.24}
\end{equation*}
$$

which is the recurrence (2.7). So it remains to check the initial condition. Now $S_{0}^{n}=S_{n}$ and it is well-known [14] that $\sum_{\sigma \in S_{n}} q^{\operatorname{maj} \sigma}=[n]_{q}$ !, so it follows from corollary 7 that

$$
a_{0}^{n}(1, q)=\sum_{\sigma \in S_{n}} q^{\operatorname{maf} \sigma}=\sum_{\sigma \in \mathcal{S}_{n}} q^{\operatorname{maj} \sigma}=[n]_{q}!.
$$

The theorem follows then from proposition 9 , since $a_{n}^{0}(x, q)$ is clearly independent of $x$.

Remark: Since (fix, maf) and (fix, maj) are not equidistributed on $S_{1}^{2}$ we cannot replace maf by maj in the above theorem.

From Corollary 7, proposition 9 and theorem 10 we derive the following result.
Corollary 11. The final sequence of the q-derangement matrix has the following interpretation:

$$
\begin{align*}
a_{0}^{n}(x, q) & =\sum_{\sigma \in \mathcal{S}_{n}} x^{\mathrm{fix} \sigma} q^{\mathrm{maf} \sigma}  \tag{4.25}\\
& =\sum_{\sigma \in \mathcal{S}_{n}} x^{\mathrm{fix} \sigma} q^{\mathrm{maj} \sigma}  \tag{4.26}\\
& =[n]_{q}!\left(1+\sum_{i=1}^{n} \frac{(x-1)(x-q) \cdots\left(x-q^{i-1}\right)}{[i]_{q}!}\right) \tag{4.27}
\end{align*}
$$

Note that the last equation has been obtained by Gessel and Reutenauer [12] and by Wachs [17] in the special $x=0$ case using different methods.

## 5. An open problem about $q$-succession numbers

Let $\sigma$ be a permutation in $S_{n}$. For convenience put $\sigma(0)=0$. We say that an element $p$ (with $1 \leq p \leq n$ ) is a succession of $\sigma$ if $\sigma(p)=\sigma(p-1)+1$. The $p$ is called the succession position, while $\sigma(p)$ is called the succession value. Let $\operatorname{SUC}(\sigma)$ be the set of succesion values of $\sigma$ and let suc $\sigma$ be the number of successions of $\sigma$. For example, if

$$
\sigma=\left(\begin{array}{lllllllll}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
1 & 4 & 3 & 8 & 9 & 5 & 6 & 7 & 2
\end{array}\right)
$$

then $\operatorname{SUC}(\sigma)=\{1,9,6,7\}$ and suc $\sigma=4$.
We use a variant of Foata's first fundamental transformation [10] to show that the statistics fix and suc are equidistributed on $\mathcal{S}_{n}$.

Given a permutation $\sigma=\sigma(1) \sigma(2) \cdots \sigma(n) \in S_{n}$ we set $\sigma^{d}=\sigma(2) \cdots \sigma(n) \sigma(1)$. We call the standard form of the factorization into cycles of $\sigma$ the unique writing $\bar{\sigma}$ such that in each cycle $\left(a, \sigma(a), \ldots, \sigma^{l}(a)\right)$ the maximum $\sigma^{l}(a)$ is in the last position and the cycles of $\sigma$ are decreasingly ordered according to their maxima. (Note that this is not the usual definition of standard form.) We define $\varphi(\sigma)$ as the permutation obtained by erasing the parentheses in the standard form of $\bar{\sigma}^{d}$.

The following lemma is easy to verify.
Lemma 12. The mapping $\varphi$ is a bijection on $S_{n}$ such that for all $\sigma \in S_{n}, F I X(\sigma)=$ $\operatorname{SUC}(\varphi(\sigma))$ and fix $\sigma=\operatorname{suc} \varphi(\sigma)$. Hence the statistics fix and suc are equidistributed on $S_{n}$.

For example, if $\sigma=142836759 \in \mathcal{S}_{9}$, then

$$
\sigma^{d}=428367591 \quad \text { and } \quad \bar{\sigma}^{d}=(14389)(567)(2) .
$$

Erasing the parentheses we obtain the permutation $\varphi(\sigma)=143895672$. We have

$$
\operatorname{FIX}(\sigma)=\operatorname{SUC}(\varphi(\sigma))=\{1,6,7,9\}
$$

Define the statistic

$$
\operatorname{suc}^{\prime} \sigma= \begin{cases}\operatorname{suc} \sigma, & \text { if } \sigma(1) \neq 1 \\ \operatorname{suc} \sigma-1, & \text { if } \sigma(1)=1\end{cases}
$$

and let

$$
F_{n}(x)=\sum_{\sigma \in \mathcal{S}_{n}} x^{\mathrm{fix} \sigma}, \quad S_{n}(x)=\sum_{\sigma \in \mathcal{S}_{n}} x^{\mathrm{suc} c^{\prime} \sigma}
$$

Then, using lemma 12, we obtain a bijective proof of the following known results (See [3, 15]).

Proposition 13. We have

$$
\begin{equation*}
S_{n+1}(x)=F_{n+1}(x)+(1-x) F_{n}(x), \tag{5.28}
\end{equation*}
$$

and in particular

$$
\begin{equation*}
S_{n+1}(0)=d_{n+1}+d_{n} \tag{5.29}
\end{equation*}
$$

Setting $q=1$ in (4.20) we see that

$$
\begin{equation*}
\sum_{n \geq 0} F_{n}(x) \frac{t^{n}}{n!}=\frac{e^{(x-1) t}}{1-t} \tag{5.30}
\end{equation*}
$$

Hence, from equation (5.28), we have

$$
\begin{equation*}
\sum_{n \geq 0} S_{n}(x) \frac{t^{n}}{n!}=\frac{e^{(x-1) t}}{1-t}+(1-x) \sum_{n \geq 1} F_{n-1}(x) \frac{t^{n}}{n!} \tag{5.31}
\end{equation*}
$$

in which by convention $S_{0}(x)=F_{0}(x)=1$. Thus

$$
\begin{equation*}
\sum_{n \geq 0} S_{n}(x) \frac{t^{n}}{n!}=\frac{e^{(x-1) t}}{1-t}+(1-x) \int_{0}^{t} \frac{e^{(x-1) z}}{1-z} d z \tag{5.32}
\end{equation*}
$$

Let $\mathcal{L}$ be the formal Laplace transformation on the ring of formal power series, that is, $\mathcal{L}\left(\sum a_{n} x^{n} / n!\right)=\sum a_{n} x^{n}$. Then

$$
\begin{equation*}
\sum_{n \geq 0} F_{n}(x) t^{n}=\mathcal{L}\left(\frac{e^{(x-1) t}}{1-t}\right)=\sum_{n \geq 0} \frac{n!t^{n}}{[1-(x-1) t]^{n+1}} \tag{5.33}
\end{equation*}
$$

Therefore

$$
\begin{align*}
\sum_{n \geq 0} S_{n}(x) t^{n} & =\sum_{n \geq 0} F_{n}(x) t^{n}+(1-x) \sum_{n \geq 0} F_{n}(x) t^{n+1} \\
& =[1-(x-1) t] \sum_{n \geq 0} F_{n}(x) t^{n} \\
& =\sum_{n \geq 0} \frac{n!t^{n}}{[1-(x-1) t]^{n}} \tag{5.34}
\end{align*}
$$

In the case of $q=1$, using lemma 11 , we can restate theorem 9 in terms of successions. Unfortunately, since the mapping $\varphi$ does not keep track of the maj statistic, we do not have a full interpretation in the last model.

The distribution of our statistics on $\mathcal{S}_{3}$ is as follows:

| $\sigma \backslash$ stat | maf | maj | suc | fix |
| ---: | :---: | :---: | :---: | :---: |
| 123 | 0 | 0 | 3 | 3 |
| 132 | 1 | 2 | 1 | 1 |
| 213 | 3 | 1 | 0 | 1 |
| 231 | 2 | 2 | 1 | 0 |
| 312 | 1 | 1 | 1 | 0 |
| 321 | 2 | 3 | 0 | 1 |

## Statistic distributions on $\mathcal{S}_{3}$

Finally we record two open problems related to our work.

1) Find a mahonian statistic "mag" such that (suc, mag) is equidistributed with (fix, maj) on the symmetric group $S_{n}$.
2) Generalize the statistic "maf" on permutations to words as in $[5,13]$ for other mahonian statistics.
