Outline

- 9 Model Checking
- Conclusion and Future Work

Consider the temporal logic of until and since over the real numbers model of time. This logic is an important basis for reasoning about concurrency, metric constraints and planning.

Despite its usefulness and long history, there are no existing implementable reasoning techniques for it.

We look at algorithms for deciding satisfiability, model checking and synthesis.

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

The Logics: structures and syntax

Fix a countable set \mathcal{L} of propositional atoms.

Definition

Frames (T, <), or *flows of time*, will be irreflexive linear orders. *Structures* $\mathcal{R} = (T, <, h)$ will have a frame (T, <) and a *valuation h* for the atoms i.e. for each atom $p \in \mathcal{L}$, $h(p) \subseteq T$.

The language L(U, S) is generated by the 2-place connectives U (Until) and S (Since) along with classical \neg and \land . Set of formulas contains the atoms and for formulas α and β we include $\neg \alpha$, $\alpha \land \beta$, $U(\alpha, \beta)$ and $S(\alpha, \beta)$. i.e. prefix versions of U and S: U(p, q) says that "until p is true, q holds".

・ロト ・ 四ト ・ ヨト ・ ヨト

Semantics

Formulas evaluated at points in structures $\mathcal{R} = (T, <, h)$. Usually here $(T, <) = (\mathbb{R}, <)$.

 $\mathcal{R}, x \models \alpha$ means α is true at the point $x \in T$:

| $\mathcal{R}, x \models p$ | iff | $x \in h(P)$, for p atomic; |
|---|-----|---|
| \land, \lnot | | as usual |
| $\mathcal{R}, \mathbf{x} \models \mathbf{U}(\alpha, \beta)$ | iff | there is $y > x$ in T such that $\mathcal{R}, y \models \alpha$ and |
| | | for all $z \in T$ such that $x < z < y$ |
| | | we have $\mathcal{R}, z \models \beta$; and |
| $\mathcal{R}, \mathbf{x} \models \mathbf{S}(\alpha, \beta)$ | iff | there is $y < x$ in T such that $\mathcal{R}, y \models \alpha$ and |
| | | for all $z \in T$ such that $y < z < x$ |
| | | we have $\mathcal{R}, z \models \beta$. |
| | | |

Image: A matrix

Abbreviations include the usual classical and temporal ones such as $F\alpha \equiv U(\alpha, \top)$, $G\alpha \equiv \neg F \neg \alpha$, $C^+\alpha \equiv U(\top, \alpha)$, $K^+\alpha \equiv \neg C^+(\neg \alpha)$, P, H, C^- , K^- .

Satisfiability of a formula means that there is a model and a time point when that formula is true. *Validity* defined as usual.

When $T = \mathbb{R}$ we call the logic RTL.

So we have the RTL-SAT problem.

Decidability

Eg, decide if

$$U(\top, p) \land F \neg p \land \neg U(\neg p \lor K^+(\neg p), p)$$

is satisfiable.

Decidability of RTL proved by [BG85].

Rabin's decision procedure for the second-order monadic logic of two successors [Rab69] is used in [BG85] to show that that RTL is decidable. One of the two decision procedures in that paper just gives us a non-elementary upper bound on the complexity of RTL-SAT.

< 回 > < 三 > < 三 >

Axioms

- all classical tautologies,
- the six Burgess-Xu axioms as follows:

$$egin{aligned} G(p
ightarrow q) &
ightarrow (U(p,r)
ightarrow U(q,r)) \ G(p
ightarrow q)
ightarrow (U(r,p)
ightarrow U(r,q)) \ p \land U(q,r)
ightarrow U(q \land S(p,r),r) \ U(p,q)
ightarrow U(p,q \land U(p,q)) \ U(q \land U(p,q),q)
ightarrow U(p,q) \ U(p,q) \land U(r,s)
ightarrow U(p \land r,q \land s) \lor U(p \land s,q \land s) \lor U(q \land r,q \land s) \end{aligned}$$

along with each of their duals,

plus axioms for density and no end points:
 K⁺⊤,K⁻⊤,F⊤ and P⊤

and more ...

Axioms Continued

Two for Dedekind completeness:Prior-U: $U(\top, p) \land F \neg p \rightarrow U(\neg p \lor K^+(\neg p), p)$ Prior-S: $S(\top, p) \land P \neg p \rightarrow S(\neg p \lor K^-(\neg p), p)$

and Sep:

Sep:
$$K^+ p \land \neg K^+ (p \land U(p, \neg p)) \rightarrow K^+ (K^+ p \land K^- p)$$

A (10) A (10) A (10)

Mosaics

The PSPACE RTL satisfiability decision procedure in [Rey10a] uses linear time mosaic techniques.

Mosaics [N95, MMR00, Rey03, HHM⁺99] are small pieces of a model, in our case, a small piece of a linear-flowed structure.

A mosaic = (subfmlas true at first point, subfmlas true all times in between, subfmlas true at 2nd point)

Syntactically defined with some simple closure properties.

$$A \longrightarrow B \longrightarrow C$$

| M. Rev | nolds | (UWA) |
|--------|--------|-----------|
| | 110100 | (0,0,0,0) |

Our mosaics will only be concerned with a finite set of formulas:

Definition

For each formula ϕ , define the *closure* of ϕ to be $\operatorname{Cl}\phi = \{\psi, \neg \psi \mid \psi \leq \phi\}$ where $\chi \leq \psi$ means that χ is a subformula of ψ .

We can sometimes think of $Cl\phi$ as being closed under negation: we could treat $\neg \neg \alpha$ as if it was α .

Mosaic

Definition

Suppose ϕ is from L(U, S). A ϕ -mosaic is a triple (A, B, C) of subsets of Cl ϕ such that:

- C0.1 A and C are maximally propositionally consistent, and
- C0.2 for all $\beta \in Cl\phi$ with $\neg \beta \in Cl\phi$ we have $\neg \beta \in B$ iff $\sim \beta \in B$ and the following four *coherency* conditions hold:
- C1. if $\neg U(\alpha, \beta) \in A$ and $\beta \in B$ then we have both: C1.1. $\neg \alpha \in C$ and either $\neg \beta \in C$ or $\neg U(\alpha, \beta) \in C$; and C1.2. $\neg \alpha \in B$ and $\neg U(\alpha, \beta) \in B$.
- C2. if $U(\alpha, \beta) \in A$ and $\neg \alpha \in B$ then we have both: C2.1 either $\alpha \in C$ or both $\beta \in C$ and $U(\alpha, \beta) \in C$; and C2.2. $\beta \in B$ and $U(\alpha, \beta) \in B$.
- C3-4 mirror images of C1-C2.

An example mosaic

An example mosaic for $\phi = Gp \wedge C^+(K^+q \wedge K^+(\neg q))$ is

$$(\{p, q, Gp, ..., \phi\}, \{p, Gp, K^+q, K^+(\neg q), ...\}, \{p, q, Gp, ..., \neg \phi\}).$$

Coherency conditions apply. Eg, Gp in the start implies p, Gp in the cover and p, Gp in the end.

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Mosaics can be decomposed

The example mosaic for $\phi = Gp \wedge C^+(K^+q \wedge K^+(\neg q))$ decomposes

Full decomposition means defects witnessed. Eg $\neg q$ not in cover.

M. Reynolds (UWA)

Continuous TL

Tableaux or tree like structure

We keep going to make a tree-shaped tableau of mosaics.

Patterns appear

Definition

We say that *m* is fully decomposed by the *tactic* lead σ , for some sequence σ of mosaics iff $\langle m \rangle^{\wedge} \sigma$ is a full decomposition of *m*.

The trail σ tactic is mirror.

Also a repetitive pattern called a *shuffle*.

Look at tree of patterns instead ...

Sketch RTLSAT Proof From [Rey10a]

Guess (A, B, C) for ϕ and then check that (A, B, C) is satisfiable.

In [Rey10a] satisfiability is checked via a tree of decompositions via tactics (covers getting fuller as you go down branches).

Immediately gives an EXPTIME decision procedure a la [Pra79].

By being clever in choosing decompositions, bounding the depth of a tree, can get a PSPACE result.

Theorem

RTLSAT is in PSPACE.

But the resulting tree (in case of a positive answer) looks like a sort of description of a model ...

Lead

The *lead* operation, $\mathcal{I} = \overleftarrow{\mathcal{I}_1}$ corresponds to ω submodels, each corresponding to \mathcal{I} , and each preceding the last, ...

The *trail* operator is the mirror image of the *lead* operation, whereby $\mathcal{I} = \overrightarrow{\mathcal{I}_1}$ corresponds to ω structures, each corresponding to \mathcal{I}_1 and each proceeding the earlier structures.

Shuffle

The *shuffle* operator is harder to represent with a diagram. The model expression $\mathcal{I} = \langle \mathcal{I}_1, \ldots, \mathcal{I}_n \rangle$ corresponds to a dense, thorough mixture of intervals corresponding to $\mathcal{I}_1, \ldots, \mathcal{I}_n$, without endpoints.

The shuffle operation, where $\mathcal{I} = \langle \mathcal{I}_1, \dots, \mathcal{I}_n \rangle$

Shuffles

Definition

Suppose that $(T_1, <_1, g_1), ..., (T_n, <_n, g_n)$ are linear structures. Further, suppose there is a non-empty, non-singleton linear order $(B, <_B)$ and a map $\pi : B \to \{1, ..., n\}$ such that for all b < c from B, for all $j \in \{1, ..., n\}$, there is $d \in B$ with b < d < c and $\pi(d) = j$. Then $\mathcal{T} = \sum_{b \in (B, <)} \pi(b)$ is a *shuffle* of $\{(T_i, <_i, g_i) | i = 1, ..., n\}$.

Complexity

[Rey10a] proved that RTL is PSPACE-complete (so no more complex than L(U, S) over \mathbb{N} [SC85]).

Also [Rey10b] proved US over all linear orders is PSPACE-complete.

Tableau

The tableau-like structure we saw as part of the complexity proof is the basis for a tableau for RTL but we need further work.

Define weight of a ϕ -mosaic *m* as $|Cl(\phi) \setminus cover(m)|$. So, if $|Cl(\phi)| = L$ then for every ϕ -mosaic *m*, $0 \le weight(m) \le L$, although, as the cover of a mosaic over the reals can not be inconsistent, the weight must be at least about half of *L*. Note also that *L* is bounded by the twice the length of ϕ .

Note that weight does not increase as you travel along a branch from the root: the cover of child labels is a superset of the cover of their parent.

We need to check properties of the set of nodes labelled with mosaics of a particular weight. Suppose we are looking at weight k > 0.

Look for a part of the tableau with these properties

Definition

Mosaic tableau T is a \mathbb{R} -tableau iff it satisfies the following conditions:

- T has no units, i.e. every mosaic has a decomposition into at least two mosaics;
- 2 T has no central sticks;
- T has no shuffles without a singleton; and
- T only has shuffles with concise edges.

These are essentially simple graph-theoretic properties of the labels on the decomposition tree but we will not define them in this talk.

Theorem

L(U, S) formula ϕ is \mathbb{R} -satisfiable iff ϕ has a successful \mathbb{R} -tableau.

By guessing a tableau of double exponential size we have a decision procedure that runs in 2-NEXPTIME.

Synthesis: What we want

We want an algorithm which does the following ...

Given a satisfiable formula such as $\phi = U(q \wedge K^+ p \wedge GS(p, \neg p), \neg U(q, \neg q) \wedge \neg U(q, q)).$

Output a finite description of a model (any model) of ϕ .

Eg picture ...

3

• • • • • • • • • • • • •

Model Expressions

First, though, any synthesis algorithm will need to output the description of a particular temporal structure over the reals (although we don't care up to order-preserving isomorphism). Model Expressions are an abstract syntax for defining (general linear) models that are constructed using the following set of primitive operators:

$$\mathcal{I} ::= a \mid \mathcal{I} + \mathcal{J} \mid \overrightarrow{\mathcal{I}} \mid \overleftarrow{\mathcal{I}} \mid \langle \mathcal{I}_0, ..., \mathcal{I}_n \rangle$$

where $a \in \Sigma = \wp(\mathcal{L})$

so letter indicates the atoms true at a point.

We refer to these operators, respectively, as a letter, concatenation, lead, trail, and shuffle.

Correspondence

Definition

A model expression \mathcal{I} corresponds to a structure as follows:

- λ is the empty expression and corresponds to the empty structure (Ø, <, h) where < is the empty relation and h(p) = Ø for all p ∈ L.
- a corresp. to a single point structure ({x}, <, h) where x is any object, < is the empty relation and h(p) = {x} if and only if p ∈ a.
- *I* + *J* corresponds to any structure isomorphic to **T** ⊕ **S**, for some structure **T** which corresponds to *I* and **S** which corresponds to *J*.
- $\overline{\mathcal{I}}$ corresp. to any structure iso. to $\Sigma_{(\mathbb{N},>)}\mathcal{X}_t$ where, for all $t \in \mathbb{N}$, $\mathcal{X}_t = \mathcal{X}$ is some structure corresponding to \mathcal{I} . (Trail is mirror).
- For the case of shuffle, say *I* = ⟨*I*₁, ..., *I_n*⟩, and suppose that for each *i* = 1, ..., *n*, *X_i* corresponds to *I*. Now define *s* : ℚ → ⟨*I*₁, ..., *I_n*⟩ by: if *t* ∈ *Q_i* ⊆ ℚ then *s*(*t*) = *X_i*; otherwise—if *t* ∈ ℚ \ ⋃_{*i*≤*n*} *Q_i*—define *s*(*t*) = *X*₁. Then *I* corresponds to any structure isomorphic to Σ_(ℚ,<)*s*(*t*).

Lead

The *lead* operation, $\mathcal{I} = \overleftarrow{\mathcal{I}_1}$ corresponds to ω submodels, each corresponding to \mathcal{I} , and each preceding the last, ...

The *trail* operator is the mirror image of the *lead* operation, whereby $\mathcal{I} = \overrightarrow{\mathcal{I}_1}$ corresponds to ω structures, each corresponding to \mathcal{I}_1 and each proceeding the earlier structures.

Shuffle

The *shuffle* operator is harder to represent with a diagram. The model expression $\mathcal{I} = \langle \mathcal{I}_1, \ldots, \mathcal{I}_n \rangle$ corresponds to a dense, thorough mixture of intervals corresponding to $\mathcal{I}_1, \ldots, \mathcal{I}_n$, without endpoints.

The shuffle operation, where $\mathcal{I} = \langle \mathcal{I}_1, \dots, \mathcal{I}_n \rangle$

RMEs

Only want to build separable, dense struct. w/out endpoints...

Definition (Real Model Expression)

$$\mathcal{K} ::= \langle a_0, ..., a_m, x_1 + \mathcal{K}_1 + y_1, ..., x_n + \mathcal{K}_n + y_n \rangle \mid \mathcal{K}_0 + a + \mathcal{K}_1 \mid \overrightarrow{a + \mathcal{K}} \mid \overleftarrow{\mathcal{K} + a}$$

where $a, a_i, x_i, y_i \in \wp \mathcal{L}$, and $m, n \ge 0$

The letter a_0 can be later used as a sort of background filler to ensure that the shuffle is Dedekind complete.

RMEs always define open intervals. Base element of recursion is shuffle with only points. Will define a dense, separable linear order with all letters homogeneously distributed.

< 口 > < 同 > < 回 > < 回 > < 回 > <

Non correspondence

Lemma

Every real model expression corresponds to some structure whose frame is dense, separable and without end-points.

However, ...

These structures do not have a real frame: they're countable. Luckily, there is an iterative way of constructing a particular real-flowed structure for each RME...

A B F A B F

$R(\mathcal{I})$ Definition ($\mathcal{R}(\mathcal{I})$)

Suppose \mathcal{I} is a model expression. We define a particular structure $\mathcal{R}(\mathcal{I})$ inductively and depending on the form of \mathcal{I} as follows.

- $\mathcal{R}(\lambda) = (\emptyset, \emptyset, h)$, where $h(p) = \emptyset$ for every $p \in \mathcal{L}$.
- For a letter a, R(a) = ({0}, Ø, h), where for each p ∈ L, h(p) = {0} if p ∈ a and h(p) = Ø otherwise.
- If \mathcal{I}_1 and \mathcal{I}_2 are model expressions, then $\mathcal{R}(\mathcal{I}_1 + \mathcal{I}_2) = \mathcal{R}(\mathcal{I}_1) \oplus \mathcal{R}(\mathcal{I}_2).$
- If \mathcal{I} is a model expression then $\mathcal{R}(\mathcal{I}) = \Sigma_{(\mathbb{N},>)} \mathcal{X}_t$ where $\mathcal{X}_t = \mathcal{R}(\mathcal{I})$ for each $t \in \mathbb{N}$.
- $\mathcal{R}(\vec{\mathcal{I}})$ is analogously based on $(\mathbb{N}, <)$.
- For the case of shuffle, say $\mathcal{I} = \langle \mathcal{I}_1, ..., \mathcal{I}_n \rangle$, define $f : \mathbb{R} \to \langle \mathcal{I}_1, ..., \mathcal{I}_n \rangle$ by: if $t \in Q_i \subseteq \mathbb{Q}$ then $f(t) = \mathcal{I}_i$; otherwise—if $t \in \mathbb{R} \setminus \bigcup_{i \leq n} Q_i$ —define $f(t) = \mathcal{I}_1$. Define $\mathcal{R}(\mathcal{I}) = \Sigma_{(\mathbb{R},<)} \mathcal{R}(f(t))$.

Actually a real model

Lemma

For every real model expression \mathcal{K} , $R(\mathcal{K})$ is a structure with a frame that is isomorphic to the reals.

Synthesis for RTL

Results from French, McCabe-Dansted and Reynolds [FMDR13].

Theorem

There is an FPSPACE procedure which given a formula ϕ from L(U, S) will decide whether ϕ is R-satisfiable or not and, if so, will provide a real model expression for a model of ϕ .

Theorem

The complexity of the problem of providing a real model expression for a model of formulas of L(U,S) is FPSPACE-complete.

A B K A B K

Example

We now have an algorithm which does the following ...

Given a satisfiable formula such as $\phi = U(q \wedge K^+ p \wedge GS(p, \neg p), \neg U(q, \neg q) \wedge \neg U(q, q)).$

It outputs finite description of some model of ϕ .

$$\langle \{\boldsymbol{p},\boldsymbol{q}\}\rangle + \{\boldsymbol{p},\boldsymbol{q}\} + \langle \{\boldsymbol{p},\boldsymbol{q}\}, \{\boldsymbol{p}\}\rangle + \{\boldsymbol{p},\boldsymbol{q}\} + \overline{\{\boldsymbol{p},\boldsymbol{q}\} + \langle \{\boldsymbol{q}\}\rangle}$$

Regular Model Expressions (RegMEs) are similar to model expressions but also allow the *Kleene star* "*" and *or* "|" operators, resulting in the following syntax:

$$\mathcal{I} ::= \nu \mid \lambda \mid (\mathcal{I} + \mathcal{I}) \mid (\mathcal{I} | \mathcal{I}) \mid \mathcal{I} * \mid \overleftarrow{\mathcal{I}} \mid \overrightarrow{\mathcal{I}} \mid \langle \mathcal{I}_1, \dots, \mathcal{I}_n \rangle$$

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

RegME Accepting a structure

MEs *correspond* to a particular structures that are all elementary equivalent. However, RegMEs are more like automata in that the structures accepted by a single RegMEs need not be elementary equivalent. For this reason we use the term "accept" rather than "correspond", unlike previous papers that only deal with MEs.

RegME Accepting a structure (continued)

Definition

A model expression \mathcal{I} accepts structures as follows:

- λ is the empty expression and accepts the empty structure (Ø, <, h) where < is the empty relation and h(p) = Ø for all p ∈ L.
- *ν* accepts any single point structure ({x}, <, h) where x is any
 object, < is the empty relation and h(p) = {x} if and only if p ∈ ν.

- *I* + *J* accepts any structure isomorphic to **T** ⊕ **S**, for some structure **T** which is accepted by *I* and **S** which is accepted by *J*.
- $\overleftarrow{\mathcal{I}}$ accepts any structure isomorphic to $\Sigma_{(\mathbb{N},>)}X_t$ where, for all $t \in \mathbb{N}, X_t = X$ is some structure accepted by \mathcal{I} . (trail mirror)
- ⟨*I*₁,...,*I_n*⟩ accepts a structure if it is isomorphic to some Σ_(T,<)*X_t* where: (*T*, <) is a dense non-empty linear order without end-points; there is a function *f* from *T* to {1,...,*n*} such that for every *x*, *y* ∈ *T*, for every *i* ∈ {1,...,*n*}, if *x* < *y* then there is *z* ∈ *T* such that *x* < *z* < *y* and *f*(*z*) = *i*; additionally for all *t* ∈ *T* we have *X_t* accepted by *I_{f(t)}*.

M. Reynolds (UWA)

RegME Accepting a structure (continued)

Definition

Now we define the regular operators:

- $\mathcal{I}|\mathcal{J}$ accepts any structure that is accepted by either \mathcal{I} or \mathcal{J} .
- *I** accepts any structure that accepted by λ, *I*, *I* + *I*, or *I* + *I* + *I* and so on.

A (10) A (10) A (10)

Model Checking

(Regular) Model expressions also allow us to do model checking with RTL.

Definition

We define the *RegME-checking problem* as follows: given a RegME \mathcal{I} and formula ϕ , determine whether \mathcal{I} accepts a structure $\mathbf{T} = (\mathbf{T}, <, \mathbf{h})$ containing an $x \in T$ such that $\mathbf{T}, \mathbf{x} \models \phi$.

Note that when \mathcal{I} accepts all structures, this becomes equivalent to testing satisfiability of ϕ . For example if $\mathcal{I} = \langle \lambda, \emptyset, \{p\}, \{q\}, \{p,q\} \rangle$ then model checking a formula ϕ over the atoms $\{p,q\}$ against \mathcal{I} is equivalent to checking the satisfiability of ϕ . Since satisfiability checking RTL is PSPACE-complete, this may suggest another way of showing that our model checking problem is PSPACE-hard; however, note that the length of the RegME that accepts all structures is exponential in the number of atoms.

< 日 > < 同 > < 回 > < 回 > < □ > <

From McCabe-Dansted, Reynolds and French, TIME 2016, algorithm reduces the model checking problem into an RTL satisfiability problem.

The basic idea is that satisfiability checking linear time temporal logics is in PSPACE. Thus, we can model check *M* against ϕ by converting the model *M* into a formula Ψ_M , and then testing the satisfiability of the conjunction of ϕ and Ψ_M . We will introduce some dummy points, so we will have to modify ψ slightly to skip over those points.

Theorem

Our model checking procedure is sound and complete.

Lemma

Model Checking RegMEs is in PSPACE.

Conclusion and Future Work

We considered synthesizing, or constructing, a monadic structure over the reals, from a given first-order specification.

Presented notation for giving a manageable description of the compositional construction of such a model.

Used mosaics and separation techniques to give an algorithm for synthesis.

Future Work:

Implementation via tableaux (at least the temporal synthesis part). How many "different" models? Using regular expressions to describe all models.

Adding metric restrictions.

Thank you for listening
