#### Gargnano, August 20-25, 2012

< ロ > < 同 > < 回 > < 回 >

- Most fragments of HS (and CDT) are undecidable on most of the interesting classes of interval structures.
- Still, some pockets of decidability remain.
- Various decidability results are based on some semantic restrictions reducing the interval-based semantics to point-based.
- But there are some quite non-trivial decidable cases of interval logics with genuinely interval-based semantics.
- This lecture will give an overview of decidable interval logics.

- Locality: an atomic proposition is true over an interval if and only if it is true at its starting point.
- Homogeneity: an atomic proposition is true over an interval if and only if it is true at every subinterval / every point in that interval.
- Convexity: if a formula is true on two overlapping intervals, then it is true on their union.
- Considering incomplete interval structures, e.g., split structures, where every interval can be chopped in a unique way (thus creating a tree-like subinterval structure).

There exist a few cases of (genuine) interval logics which can be easily checked:

- the fragment *BB* of HS is essentially point-based, because the left endpoint of the current interval remains fixed;
- similarly, the fragment *EE* of HS is essentially point-based, because the left endpoint of the current interval remains fixed.

There exist a few cases of (genuine) interval logics which can be easily checked:

M. Otto, *Two Variable First-order Logic Over Ordered Domains*, Journal of Symbolic Logic, 66(2):685–702, 2001

More precisely, Otto proved the decidability of the satisfiability problem for  $FO^2[<]$  on the classes of all linear orders, of well-orders, and of finite linear orders, as well as on the linear order on the natural numbers.

His proofs are based on an elaborated model-theoretic argument, analyzing the types of elements and pairs in models of  $FO^2[<]$ .

Decidability of  $A\overline{A}^{\pi+}$  on each of these classes immediately follows.

Moreover, since  $A\overline{A}^+$  and  $A\overline{A}^-$  are strictly less expressive than  $A\overline{A}^{\pi+}$ , their decidability on the same classes of structures immediately follows  $(A\overline{A}^-$  can be naturally embedded into  $A\overline{A}^{\pi+}$  via the translation clauses  $\tau(\langle A \rangle \varphi) = \diamondsuit_r(\neg \pi \land \tau(\varphi))$  and  $\tau(\langle \overline{A} \rangle \varphi) = \diamondsuit_l(\neg \pi \land \tau(\varphi))$ .

More precisely, Otto proved the decidability of the satisfiability problem for  $FO^2[<]$  on the classes of all linear orders, of well-orders, and of finite linear orders, as well as on the linear order on the natural numbers.

His proofs are based on an elaborated model-theoretic argument, analyzing the types of elements and pairs in models of  $FO^2[<]$ .

Decidability of  $A\overline{A}^{n+}$  on each of these classes immediately follows.

Moreover, since  $A\overline{A}^+$  and  $A\overline{A}^-$  are strictly less expressive than  $A\overline{A}^{\pi+}$ , their decidability on the same classes of structures immediately follows  $(A\overline{A}^-$  can be naturally embedded into  $A\overline{A}^{\pi+}$  via the translation clauses  $\tau(\langle A \rangle \varphi) = \diamondsuit_t(\neg \pi \land \tau(\varphi))$  and  $\tau(\langle \overline{A} \rangle \varphi) = \diamondsuit_t(\neg \pi \land \tau(\varphi))$ .

Hereafter, we denote interval logic(s) of temporal neighborhood by PNL.

Angelo Montanari (DIMI)

This is not the end of the story as (i) it is far from being trivial to extract a decision procedure from Otto's proof, and (ii) some meaningful cases are missing (dense linear orders, weakly discrete linear orders)

Tableau-based decision procedures have been developed for various propositional interval logics of temporal neighborhood, including:

 the future fragment of PNL (Right PNL, RPNL for short) interpreted over ⟨ℕ, <⟩ (or over a prefix of it)</li>

D. Bresolin, A. Montanari, and G. Sciavicco, *An Optimal Decision Procedure for Right Propositional Neighborhood Logic*, Journal of Automated Reasoning, 38(1-3):173–199, 2007

### The decision procedure for RPNL partly resembles that for (future) LTL

The decision procedure for (future) LTL takes advantage of the fix-point definition of temporal operators (expansion rules), which splits every temporal formula into a (possibly empty) part related to the current state and a part related to the next state, and completely forgets the past

Expansion rules

$$Gp = p \land XGp; Fp = p \lor XFp; pUq = q \lor (p \land X(pUq))$$

The decision procedure for RPNL must keep track of universal requests as well as pending existential requests coming from the past

## The nodes of the graph

For any interval  $[d_i, d_j]$ ,  $A_{[d_i, d_j]}$  is the set of all and only the formulas that hold over it (the formula to be tested must belong to  $A_{[d_0, d_1]}$ )

## The edges of the graph

For any pair of adjacent intervals  $[d_i, d_j]$  and  $[d_j, d_k]$ , there exists an edge that links  $A_{[d_i, d_j]}$  to  $A_{[d_j, d_k]}$ .

## Graph construction

The construction starts from the node  $A_{[d_0,d_1]}$  corresponding to the initial interval  $[d_0, d_1]$ .

At the *j*-th step, it adds all nodes  $A_{[d_i,d_j]}$ , with i < j (and the relevant edges).

### Constraint 1

If  $[A]\psi$  belongs to  $A_{[d_i,d_j]}$ , then  $\psi$  must belong to  $A_{[d_i,d_k]}$ .

## **Constraint 2**

Since every right neighbor of  $[d_i, d_k]$  is a right neighbor of  $[d_j, d_k]$ ,  $A_{[d_i, d_k]}$  and  $A_{[d_j, d_k]}$  must agree on their (universal and existential) temporal formulas.

イロト 不得 トイヨト イヨト

How do we guarantee that existential temporal requests are eventually satisfied?

If, after the execution of the *i*-th step, there still exists a pending existential temporal request, that is, a  $\langle A \rangle \psi$  formula belonging to a node  $A_{[d_h,d_j]}$  such that there exists no node  $A_{[d_j,d_k]}$  including  $\psi$ , we (try to) satisfy it by adding a new node  $A_{[d_j,d_{i+1}]}$  (in fact, a new bunch of nodes  $A_{[d_0,d_{i+1}]}, \ldots, A_{[d_i,d_{i+1}]}$ ) and the relevant edges.

#### How do we guarantee termination?

New nodes may introduce new existential temporal requests.

Such a model building process can be turned into an effective procedure.

#### Problem

Interval structures satisfying  $\varphi$  may be arbitrarily large or even infinite.

## A small (pseudo)model theorem for RPNL over $\langle \mathbb{N}, < angle$

**Result 1.** We give a bound on the size of finite interval structures that must be checked for satisfiability, when searching for finite  $\varphi$ -models

**Result 2.** We show that we can restrict ourselves to infinite interval structures with a finite bounded representation, when searching for infinite  $\varphi$ -models.

- The removal of a point *d<sub>e</sub>* causes the removal of all intervals either beginning or ending at it.
- Since RPNL features only future time modalities, the removal of intervals beginning at d<sub>e</sub> is not critical.
- The removal of intervals ending at *d<sub>e</sub>* may introduce "defects".
- By properly choosing the point d<sub>e</sub> to remove, we can guarantee that there exist sufficiently many points in the future of d which allows us to fix such defects.

# The tableau system for RPNL over $\langle \mathbb{N}, < \rangle$

Tableau construction is based on two expansion rules:

- step rule
- fill-in rule

and a blocking condition, that guarantees termination.

It does not need to differentiate the search for a finite model from that for an infinite one!

#### NEXPTIME-completeness

The procedure has a nondeterministic time complexity which is exponential in the size of  $\varphi$ . Moreover, a NEXPTIME lower bound can be obtained by a reduction from the NEXPTIME-complete exponential tiling problem.

and a blocking condition, that guarantees termination.

It does not need to differentiate the search for a finite model from that for an infinite one!

#### **NEXPTIME-completeness**

The procedure has a nondeterministic time complexity which is exponential in the size of  $\varphi$ . Moreover, a NEXPTIME lower bound can be obtained by a reduction from the NEXPTIME-complete exponential tiling problem.

In the case of full PNL, the removal process is still possible, but it turns out to be much more involved.

## Complications

- The removal of a point *d* from a PNL model may affect the satisfiability of formulae over intervals in the past as well as in the future of *d*.
- To fix the defects possibly caused by the removal of *d*, one must guarantee that there exist sufficiently many points with the same characteristics as *d* both in the future and in the past of *d*.
- Moreover, one must guarantee that changing the valuation of intervals that either end or start at these points does not generate new defects.

### Theorem

The decision problem for PNL over  $\langle \mathbb{Z}, < \rangle$  is NEXPTIME-complete.

Angelo Montanari (DIMI)

In the case of full PNL, the removal process is still possible, but it turns out to be much more involved.

#### Theorem

There exist RPNL formulae that cannot be satisfied over  $\langle \mathbb{N}, < \rangle$ , but turn out to be satisfiable over other linearly-ordered domains.

## The formula AccPoints

$$\begin{split} [G]\psi &= \psi \wedge [A]\psi \wedge [A][A]\psi\\ seq_p &= p \rightarrow \langle A \rangle p\\ \textit{AccPoints} &= \langle A \rangle p \wedge [G]seq_p \wedge \langle A \rangle [G] \neg p \end{split}$$

The formula *AccPoints* is unsatisfiable over  $(\mathbb{N}, <)$ , but it is satisfiable over the class of all linear orders.

There exist RPNL formulae that cannot be satisfied over  $\langle \mathbb{N}, < \rangle$ , but turn out to be satisfiable over other linearly-ordered domains.

The formula AccPoints		
$[G]\psi$ =	=	$\psi \wedge [{m{A}}]\psi \wedge [{m{A}}][{m{A}}]\psi$
seq <sub>p</sub> =	=	$ ho ~ ightarrow~ \langle A  angle  ho$
AccPoints =	=	$\langle A  angle  ho \wedge [G] seq_{ ho} \wedge \langle A  angle [G]  eg  ho$

The formula *AccPoints* is unsatisfiable over  $(\mathbb{N}, <)$ , but it is satisfiable over the class of all linear orders.

< 回 ト < 三 ト < 三

$$\textit{AccPoints} = \langle \textit{A} \rangle \textit{p} \land [\textit{G}] \textit{seq}_{\textit{p}} \land \langle \textit{A} \rangle [\textit{G}] \neg \textit{p}$$

Every model of *AccPoints* contains at least one accumulation point  $d_{\omega}$  placed after an infinite sequence of points:

#### Theorem

The decision problem for RPNL over all linear orders is NEXPTIME-complete.

Angelo Montanari (DIMI)

A (10) A (10)

▷ All (standard) models are infinite.

▷ Every model can be assumed to be built on the rational interval [0,1].

▷ The tableaux require special looping control mechanism to guarantee termination.

▷ Open terminating tableaux do not produce models, but only finite pseudo-models, which then are expanded to infinite standard models.

▷ Thus, there are three stages in proving satisfiability of a formula in a dense subinterval structure:

open saturated tableau  $\Rightarrow$  pseudo-model  $\Rightarrow$  standard model.

Both transitions are provably successful and constructive, thus reducing the task to the construction of an open saturated tableau for the formula.

#### **Syntax**

$$\varphi ::= p \mid \neg \varphi \mid \varphi \lor \varphi \mid \varphi \land \varphi \mid \langle D \rangle \varphi$$

A model for  $D_{\sqsubset}$  is a pair  $\langle \langle \mathbb{I}(\mathbf{D})^{-}, D \rangle, V \rangle$  where

- $\langle \mathbb{I}(\mathbf{D})^{-}, D \rangle$  is a dense subinterval structure
- *V* is a valuation function that assigns to every propositional variable *p* a set of intervals

### Semantics

•  $\langle D \rangle \varphi$  is true on [a, b] iff there exists  $[c, d] \subseteq [a, b]$  where  $\varphi$  holds.

(REFL) 
$$\frac{[D]\psi, F}{\psi, [D]\psi, F}$$

э

< 回 > < 三 > < 三 >

- Apply once the (STEP) rule:  $\begin{bmatrix}
   D]\psi_1, \dots, [D]\psi_m, \\
   \langle D\rangle\varphi_1, \dots, \langle D\rangle\varphi_n, F
  \end{bmatrix}$   $\hline
   \varphi_1, \psi_1, \dots, \psi_m, [D]\psi_1, \dots, [D]\psi_m | \\
   \dots \\
   | \varphi_i, \psi_1, \dots, \psi_m, [D]\psi_1, \dots, [D]\psi_m | \\
   \dots \\
   | \varphi_n, \psi_1, \dots, \psi_m, [D]\psi_1, \dots, [D]\psi_m$
- Proceed recursively in the expansion

A (10) × (10) × (10) ×

## Looping condition

When the application of the 2-DENS rule to a node *n* would generate a new reflexive node such that there exists another reflexive node n' in the tableau with the same set of temporal formulas, add an edge from *n* to *n'* instead of generating such a new node.

A node *n* in a tableau is closed if one of the following conditions holds:

- there exists a formula  $\psi$  such that  $\psi$ ,  $\neg \psi \in n$ ;
- In the tableau construction, the NOT, OR, AND, 2-DENS, or REFL rules has been applied to *n* and *all* the immediate successors of *n* are closed;
- in the tableau construction, the STEP rule has been applied to n and at least one of the immediate successors of n is closed.
- A tableau is closed iff the root is closed, otherwise it is open.

### Theorem (Soundness and completeness)

A formula  $\varphi$  is satisfiable if and only if its tableau is open

3

A node *n* in a tableau is closed if one of the following conditions holds:

- there exists a formula  $\psi$  such that  $\psi, \neg \psi \in n$ ;
- In the tableau construction, the NOT, OR, AND, 2-DENS, or REFL rules has been applied to *n* and *all* the immediate successors of *n* are closed;
- in the tableau construction, the STEP rule has been applied to n and at least one of the immediate successors of n is closed.
- A tableau is closed iff the root is closed, otherwise it is open.

### Theorem (Soundness and completeness)

A formula  $\varphi$  is satisfiable if and only if its tableau is open

3
- $\bullet\,$  Every node has a number of successors that is bounded by  $|\varphi|$
- The length of every path without repetition is linear in  $|\varphi|$
- $\Rightarrow$  The tableau can be explored using a polynomial amount of space.

• The logic is PSPACE-hard: the validity problem for prenex quantified boolean formulas can be reduced to the satisfiability problem for  $D_{\rm E}$ 

 $\Rightarrow$  The proposed method is of optimal complexity (PSPACE).

# The logic $D_{\Box}$ of the proper subinterval relation

#### The case of $D_{\Box}$ is much more complex than that of $D_{\Xi}$ .

▷ The main complication is the presence of three distinct types of proper subintervals of the current interval: beginning, ending, and middle.

 $\triangleright$  Formulas of  $\mathsf{D}_\square$  can impose conditions on the type of subintervals needed to satisfy subformulas.

For instance, the formula

#### $\langle D \rangle (p \land [D]q) \land \langle D \rangle (p \land [D] \neg q) \land [D] \neg (\langle D \rangle (p \land [D]q) \land \langle D \rangle (p \land [D] \neg q))$

forces *p* to be true at some beginning and at some ending subinterval.

 $\triangleright$  This brings additional complications on the construction of the tableau and makes the pseudo-models for D<sub> $\Box$ </sub> quite complicate.

#### The general case is still open.

イロト 不得 トイヨト イヨト

The logic of subinterval structures on discrete linear orders (as well as on finite linear orders) has been recently shown to be undecidable.

J. Marcinkowski and J. Michaliszyn, The Ultimate Undecidability Result for the Halpern-Shoham Logic, LICS 2011

The general case is still open.

It can combine the dense and discrete case in a recurrently interleaving way.

< 日 > < 同 > < 回 > < 回 > < □ > <

The logic of subinterval structures on discrete linear orders (as well as on finite linear orders) has been recently shown to be undecidable.

J. Marcinkowski and J. Michaliszyn, *The Ultimate Undecidability Result for the Halpern-Shoham Logic*, LICS 2011

The general case is still open.

It can combine the dense and discrete case in a recurrently interleaving way.

As an example, consider the formula

$$\langle D \rangle \langle D \rangle \top \wedge [D](\langle D \rangle \top \rightarrow \langle D \rangle \langle D \rangle \top \wedge \langle D \rangle [D] \bot)$$

It has neither discrete nor dense models, but it is satisfiable in Cantor's space.
