

# Model checking for LTL (= satisfiability over a finite-state program)

Angelo Montanari

Department of Mathematics and Computer Science  
University of Udine, Udine Italy

## $P$ -validity and $P$ -satisfiability problems (of $\varphi$ )

**$P$ -validity** problem (of  $\varphi$ )

**Main question:** given a finite-state program  $P$  and a formula  $\varphi$ , is  $\varphi$   $P$ -valid, that is, do all  $P$ -computations satisfy  $\varphi$ ?

**$P$ -satisfiability** problem (of  $\varphi$ )

**Main question:** given a finite-state program  $P$  and a formula  $\varphi$ , is there a  $P$ -computation which satisfies  $\varphi$ ?

To determine whether  $\varphi$  is  $P$ -valid, it suffices to employ an algorithm for deciding if there is a  $P$ -computation which satisfied  $\neg\varphi$ .

The algorithm for solving the  $P$ -satisfiability of  $\varphi$  makes use of the tableau for  $\varphi$   $T_\varphi$

## Basic definitions

- For each atom  $A$ , let  $state(A)$  be the conjunction of all state formulas in  $A$  (by  $R_{sat}$ ,  $state(A)$  must be satisfiable).
- Atom  $A$  is **consistent** with state  $s$  if  $s \models state(A)$ , that is, all state formulas in  $A$  are satisfiable by  $s$ .
- Let  $\theta : A_0, A_1, \dots$  be a path in  $T_\varphi$  and let  $\sigma : s_0, s_1, \dots$  be a computation of  $P$ .  $\theta$  is **trail** of  $T_\varphi$  over  $\sigma$  if  $A_j$  is consistent with  $s_j$ , for all  $j \geq 0$ .
- For each atom  $A \in T_\varphi$ ,  $\delta(A)$  denotes the set of successors of  $A$  in  $T_\varphi$ .

## The behavior graph

Given a finite-state program  $P$  and an LTL formula  $\varphi$ , we construct the **behavior graph** of  $(P, \varphi)$ , denoted  $\mathcal{B}_{(P, \varphi)}$ , as the product of the graph for  $P$  ( $G_P$ ) and the tableau for  $\varphi$  ( $T_\varphi$ ).

- **nodes**  $(s, A)$ , where  $s$  is a state of  $P$  and  $A$  is an atom consistent with  $s$ ;
- there exists a  $\tau$ -**labeled edge** from  $(s, A)$  to  $(s', A')$  only if  $s' = \tau(s)$  ( $s'$  is a  $\tau$ -successor of  $s$ ) and  $A' \in \delta(A)$  in the pruned tableau  $T_\varphi$  ( $A'$  is a successor of  $A$  in  $T_\varphi$ );
- **initial  $\varphi$ -nodes** are pairs  $(s, A)$ , where  $s$  is an initial state for  $P$ ,  $A$  is an initial  $\varphi$ -atom in  $T_\varphi$  (that is,  $\varphi \in A$ ), and  $A$  is consistent with  $s$ .

# Algorithm BEHAVIOR-GRAPH to construct $\mathcal{B}_{(\mathcal{P},\varphi)}$

## Algorithm **BEHAVIOR-GRAPH**

- Place in  $\mathcal{B}_{(\mathcal{P},\varphi)}$  all initial  $\varphi$ -nodes  $(s, A)$
- Repeat until no new nodes or new edges can be added the following steps.

Let  $(s, A)$  be a node in  $\mathcal{B}_{(\mathcal{P},\varphi)}$ , let  $\tau \in \mathcal{T}$  be a transition, and let  $(s', A')$  be a pair such that: (i)  $s'$  is a  $\tau$ -successor of  $s$ ,  $A' \in \delta(A)$  in the pruned tableau  $T_\varphi$ , and  $A'$  is consistent with  $s'$ .

- Add  $(s', A')$  to  $\mathcal{B}_{(\mathcal{P},\varphi)}$ , if it is not already there.
- Draw a  $\tau$ -edge from  $(s, A)$  to  $(s', A')$  if it not already there.

# An example: the system LOOP

The system **LOOP**

Initially  $x = 0$

Transitions: (i) the idling transition  $\tau_I$  and (ii) a transition  $\tau$ , with transition relation  $\rho_\tau : x' = (x + 1) \bmod 4$

The set of weakly fair (just) transitions is  $\mathcal{J} = \{\tau\}$

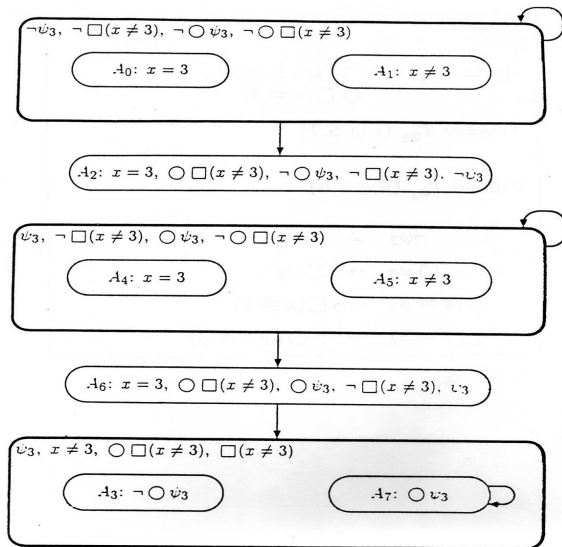

Let us consider the LTL formula  $\psi : \diamond \square (x \neq 3)$

In the next transparencies, we respectively provide the state-transition graph  $G_{LOOP}$ , the pruned tableau  $T_\psi$ , and the behavior graph  $\mathcal{B}_{(LOOP, \psi)}$ .

# The state-transition graph of system LOOP ( $G_{LOOP}$ )

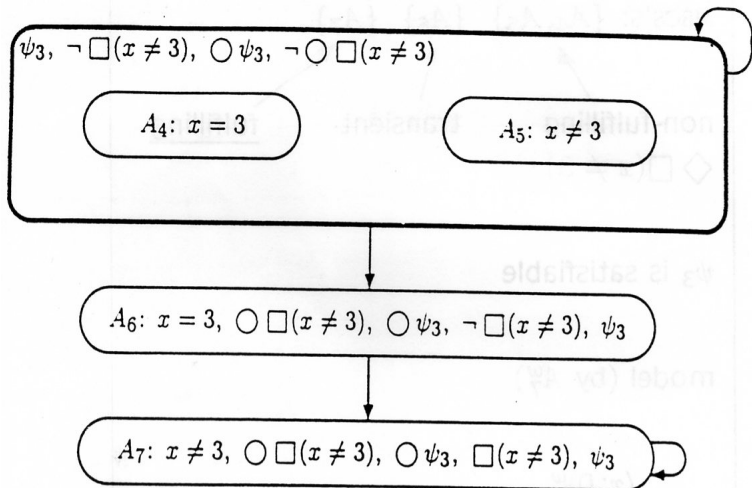

# The complete tableau

## The pruned tableau ( $T_\psi$ )

# The behavior graph $\mathcal{B}_{(LOOP, \psi)}$

## Paths in the behavior graph $\mathcal{B}_{(\mathcal{P}, \varphi)}$

### Proposition.

Let  $\varphi$  be an LTL formula.

The infinite sequence  $\pi : (s_0, A_0)(s_1, A_1) \dots$ , where  $(s_0, A_0)$  is an initial  $\varphi$ -node, is a path in  $\mathcal{B}_{(\mathcal{P}, \varphi)}$

if and only

- $\sigma_\pi : s_0 s_1 \dots$  is a run of  $P$  (computation less fairness)
- $\theta_\pi : A_0 A_1 \dots$  is a trail of  $T_\varphi$  over  $\sigma_\pi$  (for all  $j \geq 0$ ,  $A_j$  is consistent with  $s_j$ )

### Example.

In  $\mathcal{B}_{(\text{LOOP}, \psi)}$ , the path  $\pi : (s_0, A_5)(s_1, A_5)(s_2, A_5)(s_3, A_4)^\omega$  induces  $\sigma_\pi : (s_0 s_1 s_2 s_3)^\omega$  (run of LOOP) and  $\theta_\pi : (A_5 A_5 A_5 A_4)^\omega$  (trail of  $T_\varphi$  over  $\sigma_\pi$ )

## $P$ -satisfiability of $\varphi$ by path

### **Proposition.**

Let  $\varphi$  be an LTL formula.

There exists a  $P$ -computation which satisfies  $\varphi$

if and only if

there is an infinite path  $\pi$  in  $\mathcal{B}_{(P,\varphi)}$ , starting from an initial  $\varphi$ -node, such that

- $\sigma_\pi$  is a fair run (computation)
- $\theta_\pi$  is a fulfilling trail over  $\sigma_\pi$

### **Example.**

The trail  $\theta_\pi : (A_5 A_5 A_5 A_4)^\omega$  is not fulfilling (both atoms  $A_5$  and  $A_4$  include  $\diamond\Box(x \neq 3)$  and  $\neg\Box(x \neq 3)$ ).

# Adequate subgraphs

Given a behavior graph  $\mathcal{B}_{(\mathcal{P}, \varphi)}$ ,

- node  $(s', A')$  is a  $\tau$ -**successor** of node  $(s, A)$  if  $\mathcal{B}_{(\mathcal{P}, \varphi)}$  contains a  $\tau$ -edge connecting  $(s, A)$  to  $(s', A')$
- transition  $\tau$  is **enabled** on node  $(s, A)$  if it is enabled on state  $s$

Given a subgraph  $S \subseteq \mathcal{B}_{(\mathcal{P}, \varphi)}$ ,

- transition  $\tau$  is **taken** in  $S$  if there exist two nodes  $(s, A)$  and  $(s', A')$  in  $S$  such that  $(s', A')$  is a  $\tau$ -successor of  $(s, A)$
- $S$  is **just** (resp., **compassionate**) if every just (resp., compassionate) transition  $\tau \in \mathcal{J}$  (resp.,  $\tau \in \mathcal{C}$ ) is either taken in  $S$  or is disabled on some nodes (resp., all nodes) in  $S$
- $S$  is **fair** if it is both just and compassionate
- $S$  is **fulfilling** if every promising formula is fulfilled by an atom  $A$  such that  $(s, A) \in S$  for some state  $s$
- $S$  is **adequate** if it is fair and fulfilling

# Adequate strongly connected subgraphs and satisfiability

## Proposition.

A finite-state program  $P$  has a computation  $\sigma$  which satisfies  $\varphi$  if and only if the behavior graph  $\mathcal{B}_{(P,\varphi)}$  has an adequate strongly connected subgraph

**Example** (LOOP and  $\psi : \diamond\Box(x \neq 3)$ ).

The behavior graph  $\mathcal{B}_{(\text{LOOP},\psi)}$  has no adequate subgraphs.

## Example (cont'd)

Let us check the maximal strongly connected subgraphs (MSCS):

- $\{(s_0, A_5), (s_1, A_5), (s_2, A_5), (s_3, A_4)\}$  is fair, but not fulfilling ( $\psi$  belongs to both  $A_4$  and  $A_5$ , and it promises  $\Box(x \neq 3)$ , but  $\Box(x \neq 3) \notin A_4, A_5$ )
- $\{(s_0, A_7)\}$ ,  $\{(s_1, A_7)\}$ , and  $\{(s_2, A_7)\}$  are fulfilling, but not fair (they are not just with respect to transition  $\tau$ )
- $\{(s_3, A_6)\}$  is neither fair (it is not just with respect to  $\tau$ ) nor fulfilling (it is transient)

Hence, there are **no adequate subgraphs** in  $\mathcal{B}_{(\text{LOOP}, \psi)}$ .  
By the last proposition, it follows that LOOP has no computation that satisfies  $\psi : \Diamond\Box(x \neq 3)$

## Another example

**Example** (LOOP and  $\phi (= \neg\psi) : \Box\Diamond(x = 3)$ ).

The pruned tableau is the following one:

## Another example (cont'd)

The behavior graph  $\mathcal{B}_{(\text{LOOP}, \phi)}$  is the following one:

## Another example (cont'd)

The subgraph  $S = \{(s_0, A_1), (s_1, A_1), (s_2, A_1), (s_3, A_0)\}$  is an **adequate subgraph**, as it is both fair ( $\tau$  is taken in  $S$ ) and fulfilling ( $\diamond(x = 3)$  belongs to both  $A_0$  and  $A_1$ , but  $x = 3$  belongs to  $A_0$ )

By the last proposition, it follows that LOOP has computation that satisfies  $\phi : \square\diamond(x = 3)$

The periodic computation  $\sigma : (s_0 s_1 s_2 s_3)^\omega$  satisfies  $\phi$ .

It induces the fulfilling trail  $\theta : (A_1 A_1 A_1 A_0)^\omega$  in  $T_\phi$ .

## How to find adequate subgraphs?

Checking MSCS' is **not enough**:

$$S' \subset S$$

$S'$  just **implies**  $S$  just

$S'$  fulfilled **implies**  $S$  fulfilled

but

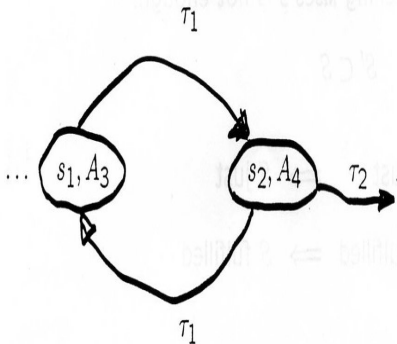

$S'$  compassionate **do not imply**  $S$  compassionate

Therefore, it is possible that  $S$  is not adequate, but  $S'$  is adequate

## A counterexample

$S'$  compassionate **do not imply**  $S$  compassionate

Let  $\tau_2$  belong to the set of compassionate transitions.  $\tau_2$  is enabled on  $s_2$  and disabled on  $s_1$

## A counterexample (cont'd)

The strongly connected subgraph  $S' = \{(s_1, A_3)\}$  is compassionate ( $\tau_2$  is disabled on all the states in this subgraph)

The strongly connected subgraph  $S = \{(s_1, A_3)(s_2, A_4)\}$ , that includes  $S'$ , is not compassionate ( $\tau_2$  is enabled on  $(s_2, A_4)$ , but it is not taken in  $S$ )

# Algorithm ADEQUATE-SUB

## Algorithm **ADEQUATE-SUB**

- accepts as input a strongly connected subgraph  $S$  and returns as output a strongly connected subgraph  $S' \subseteq S$

If  $S' = \emptyset$  -  $S$  contains no adequate subgraphs

Otherwise -  $S'$  is an adequate strongly connected subgraph in  $S$

- Notation:

$EN(\tau, S)$  - the set of all nodes  $(s, A)$  in  $S$  on which  $\tau$  is enabled

## Algorithm ADEQUATE-SUB (cont'd)

**Algorithm ADEQUATE-SUB** checks for adequate subgraphs  
**recursive function** adequate-sub( $S$ : SCS) **returns** SCS  
**if**  $S$  is not fulfilling **then return**  $\emptyset$  – failure  
**if**  $S$  is not just **then return**  $\emptyset$  – failure  
**if**  $S$  is compassionate **then return**  $S$  – success  
–  $S$  is fulfilling and just but not compassionate. Let  $T \subseteq C$   
– be the set of all compassionate transitions that are not taken  
– in  $S$ . Clearly,  $EN(T, S) \neq \emptyset$ .  
**let**  $U = S - EN(T, S)$ . Decompose  $U$  into MSCSs  $U_1 \dots U_k$ .  
**let**  $V = \emptyset, i = 1$   
**while**  $V = \emptyset$  and  $i \leq k$  **do**  
**let**  $V = \text{adequate} - \text{sub}(U_i); i := i + 1$   
**end-while**  
**return**  $V$

## An example: the system LOOP+

The system **LOOP+**

Initially  $x = 0$

LTL formula  $\psi : \diamond \square (x \neq 3)$

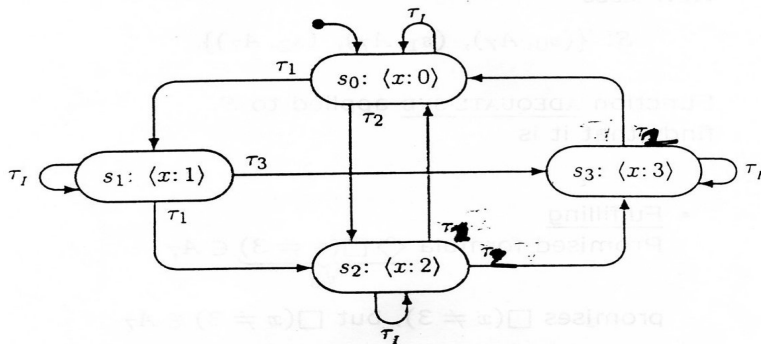

Transitions: (i) the idling transition  $\tau_I$ ; (ii)  $\mathcal{J} = \{\tau_1, \tau_2\}$ ; (iii)  $\mathcal{C} = \{\tau_3\}$

New MSCS:  $S = \{(s_0, A_7), (s_1, A_7), (s_2, A_7)\}$

In the next transparencies, we respectively provide the state-transition graph  $G_{\text{LOOP+}}$ , the pruned tableau  $T_\psi$ , and the behavior graph  $\mathcal{B}_{(\text{LOOP+}, \psi)}$ .

# The state-transition graph of system LOOP+ ( $G_{LOOP+}$ )

# The pruned tableau ( $T_\psi$ )

# The behavior graph $\mathcal{B}_{(LOOP+, \psi)}$

## Application of the function ADEQUATE-SUB

Function **ADEQUATE-SUB** applied to  $S$  finds that it is

- **fulfilling**: the formula  $\psi : \diamond\Box(x \neq 3)$ , that promises  $\Box(x \neq 3)$ , belongs to  $A_7$ , but  $\Box(x \neq 3)$  belongs to  $A_7$  as well
- **just**:  $\tau_2 \in \mathcal{J}$  is taken in  $S$  and  $\tau_1 \in \mathcal{J}$  is taken in  $S$
- **not compassionate**:  $\tau_3 \in \mathcal{C}$  is not taken in  $S$ , but it is enabled on  $(s_1, A_7)$

Construct  $U : \{(s_0, A_7), (s_2, A_7)\}$  by removing  $(s_1, A_7)$

# The subgraph $U$

20-6

## The subgraph $U$ (cont'd)

$U$  is a strongly connected subgraph (no decomposition is needed)

$U$  is adequate:

- **fulfilling** –  $A_7$  fulfills his promise  $\Box(x \neq 3)$
- **fair** –  $\tau_1$  and  $\tau_2$  are enabled  $s_2$  and  $s_0$ , respectively, and both are taken in  $U$

Hence, system LOOP<sub>+</sub> has a computation  $\sigma : (s_0 s_2)^\omega$  that satisfies  $\psi : \Diamond\Box(x \neq 3)$

## Algorithms SAT and P-SAT

To summarize ..

Algorithm **SAT** to check whether a temporal formula  $\varphi$  is satisfiable

Algorithm **P-SAT** to check the satisfiability of a formula  $\varphi$  over a program (to check whether a finite-state program  $P$  has a computation which satisfies a temporal formula  $\varphi$ )

## Algorithm P-SAT

To check whether a finite-state program  $P$  has a computation that satisfies a temporal formula  $\varphi$ , perform the following steps:

**Construct** the state-transition graph  $G_P$ .

**Construct** the pruned tableau  $T_\varphi$ .

**Construct** the behavior graph  $B_{(P,\varphi)}$ .

**Decompose**  $B_{(P,\varphi)}$  into MSCS  $S_1, \dots, S_t$ .

For each  $i = 1, \dots, t$ , **apply** algorithm **ADEQUATE-SUB** to  $S_i$ .

If any of these applications returns a nonempty result,  $P$  has a computation satisfying  $\varphi$ . This computation can be constructed by forming a path  $\pi$  that leads from an initial node to the returned adequate subgraph  $S$ , and then continues to visit each node  $S$  infinitely many times. The desired computation is the computation  $\sigma_\pi$  induced by  $\pi$ . If all applications return the empty set as result,  $P$  has no computation satisfying  $\varphi$ .

## $P$ -validity of a formula $\varphi$

To check  $P$ -validity of a formula  $\varphi$ , apply algorithm P-SAT to check whether there are  $P$ -computation satisfying  $\neg\varphi$

- If there is a  $P$ -computation satisfying  $\neg\varphi$ , then  $\varphi$  is not  $P$ -valid
- If there are no  $P$ -computations satisfying  $\neg\varphi$ , then  $\varphi$  is  $P$ -valid
