### **Model Checking: the Interval Way**

#### Angelo Montanari

Dept. of Mathematics, Computer Science, and Physics University of Udine, Italy (On leave at LaBRI - October/December 2017)

Séminaire de l'équipe Méthodes Formelles LaBRI, Talence, France November 21, 2017

## Model checking

Model checking: the desired properties of a system are checked against a model of it

- the model is usually a (finite) state-transition system
- system properties are specified by a temporal logic (LTL, CTL, CTL\* and the like)

#### Distinctive features of model checking:

- exaustive check of all the possible behaviours
- fully automatic process
- a counterexample is produced for a violated property

## Point-based vs. interval-based model checking

Model checking is usually point-based:

- properties express requirements over points (snapshots) of a computation (states of the state-transition system)
- they are specified by means of point-based temporal logics such as LTL, CTL, and CTL\*

Interval properties express conditions on computation stretches instead of on computation states

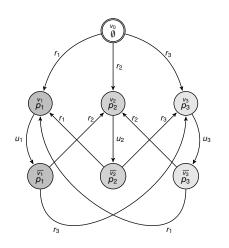

A lot of work has been done on interval temporal logic (ITL) satisfiability checking (an up-to-date survey can be found at: https://users.dimi.uniud.it/~angelo.montanari/Movep2016partl.pdf).

ITL model checking entered the research agenda only recently (Bozzelli, Lomuscio, Michaliszyn, Molinari, Montanari, Murano, Perelli, Peron, Sala)

#### Outline of the talk

- ► The model checking problem for interval temporal logics
- Complexity results: the general picture
- ► The case of the interval temporal logic AABBE (optional)
- Interval vs. point temporal logic model checking: an expressiveness comparison
- Interval temporal logic model checking with regular expressions
- Ongoing work and future developments

#### The modeling of the system: Kripke structures

- HS formulas are interpreted over (finite) state-transition systems, whose states are labeled with sets of proposition letters (Kripke structures)
- An interval is a trace (finite path) in a Kripke structure

An example of Kripke structure

## HS: the modal logic of Allen's interval relations

Allen's interval relations: the 13 binary ordering relations between 2 intervals on a linear order. They give rise to corresponding unary modalities over frames where intervals are primitive entities:

► HS features a modality for any Allen ordering relation between pairs of intervals (except for equality)

Allen rel.	HS	Definition	Example
			<i>x</i> • • <i>y</i>
meets	$\langle A \rangle$	$[x,y]\mathcal{R}_A[v,z] \iff y=v$	<i>V</i> • <i>✓ • Z</i>
before	$\langle L \rangle$	$[x,y] \mathcal{R}_L[v,z] \iff y < v$	V • — • Z
started-by	$\langleB\rangle$	$[x,y] \mathcal{R}_B[v,z] \iff x = v \land z < y$	V •
finished-by	$\langle E \rangle$	$[x,y] \mathcal{R}_{E}[v,z] \iff y = z \land x < v$	<i>V</i> •
contains	$\langle D \rangle$	$[x,y] \mathcal{R}_D[v,z] \iff x < v \land z < y$	<i>V</i> • → <i>Z</i>
overlaps	$\langle O \rangle$	$[x,y] \mathcal{R}_{\mathcal{O}}[v,z] \iff x < v < y < z$	V • — • Z

All modalities can be expressed by means of  $\langle A \rangle$ ,  $\langle B \rangle$ ,  $\langle E \rangle$ , and their transposed modalities only (if point intervals are admitted,  $\langle B \rangle$ ,  $\langle E \rangle$ , and their transposed modalities suffice)

## HS semantics and model checking

Truth of a formula  $\psi$  over a trace  $\rho$  of a Kripke structure  $\mathcal{K} =$  $(\mathcal{AP}, W, \delta, \mu, w_0)$  defined by induction on the complexity of  $\psi$ :

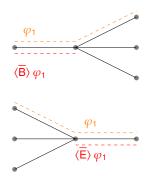

- $\blacktriangleright$   $\mathcal{K}$ ,  $\rho \models p$  iff  $p \in \bigcap_{w \in \text{states}(\rho)} \mu(w)$ , for any letter  $p \in \mathcal{AP}$ (homogeneity assumption);
- clauses for negation, disjunction, and conjunction are standard;
- $\mathcal{K}$ ,  $\rho \models \langle A \rangle \psi$  iff there is a trace  $\rho'$  s.t.  $lst(\rho) = fst(\rho')$  and  $\mathcal{K}, \rho' \models \psi$ ;
- $\blacktriangleright$   $\mathcal{K}$ ,  $\rho \models \langle \mathsf{B} \rangle \psi$  iff there is a proper prefix  $\rho'$  of  $\rho$  s.t.  $\mathcal{K}$ ,  $\rho' \models \psi$ ;
- $\triangleright$   $\mathcal{K}, \rho \models \langle \mathsf{E} \rangle \psi$  iff there is a proper suffix  $\rho'$  of  $\rho$  s.t.  $\mathcal{K}, \rho' \models \psi$ ;
- ▶ the semantic clauses for  $\langle \overline{A} \rangle$ ,  $\langle \overline{B} \rangle$ , and  $\langle \overline{E} \rangle$  are similar

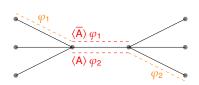

#### Model Checking

 $\mathcal{K} \models \psi \iff$  for all initial traces  $\rho$  of  $\mathcal{K}$ , it holds that  $\mathcal{K}, \rho \models \psi$ Possibly infinitely many traces!

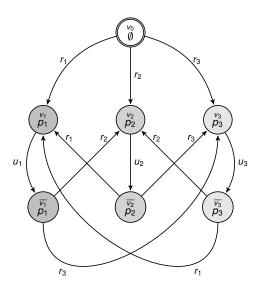

## Remark: HS state semantics (HS $_{st}$ )

According to the given semantics, HS modalities allow one to branch both in the past and in the future

#### The Kripke structure $K_{Sched}$ for a simple scheduler

### A short account of KSched

K<sub>Sched</sub> models the behaviour of a scheduler serving 3 processes which are continuously requesting the use of a common resource (it can be easily generalised to an arbitrary number of processes)

Initial state:  $v_0$  (no process is served in that state)

In  $v_i$  and  $\overline{v}_i$  the *i*-th process is served ( $p_i$  holds in those states)

The scheduler cannot serve the same process twice in two successive rounds:

- $\triangleright$  process i is served in state  $v_i$ , then, after "some time", a transition  $u_i$  from  $v_i$  to  $\overline{v}_i$  is taken; subsequently, process i cannot be served again immediately, as  $v_i$  is not directly reachable from  $\overline{V}_i$
- ▶ a transition  $r_i$ , with  $i \neq i$ , from  $\overline{v}_i$  to  $v_i$  is then taken and process *i* is served

## Some meaningful properties to be checked over $K_{Sched}$

Validity of properties over all legal computation intervals can be forced by modality [E] (they are suffixes of at least one initial trace)

Property 1: in any computation interval of length at least 4, at least 2 processes are witnessed (YES/no process can be executed twice in a row)

$$\mathcal{K}_{Sched} \models [E] \big( \langle \mathsf{E} \rangle^3 \top \to (\chi(p_1, p_2) \vee \chi(p_1, p_3) \vee \chi(p_2, p_3)) \big),$$

where  $\chi(p,q) = \langle E \rangle \langle \overline{A} \rangle p \wedge \langle E \rangle \langle \overline{A} \rangle q$ 

Property 2: in any computation interval of length at least 11, process 3 is executed at least once (NO/the scheduler can postpone the execution of a process ad libitum—starvation)

$$\mathcal{K}_{Sched} \not\models [E](\langle \mathsf{E} \rangle^{10} \top \to \langle \mathsf{E} \rangle \, \langle \overline{\mathsf{A}} \rangle \, p_3)$$

Property 3: in any computation interval of length at least 6, all processes are witnessed (NO/the scheduler should be forced to execute them in a strictly periodic manner, which is not the case)

$$\mathcal{K}_{Sched} \not\models [E](\langle E \rangle^5 \to (\langle E \rangle \langle \overline{A} \rangle p_1 \land \langle E \rangle \langle \overline{A} \rangle p_2 \land \langle E \rangle \langle \overline{A} \rangle p_3))$$

## Model checking: the key notion of $BE_k$ -descriptor

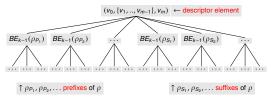

- ▶ The BE-nesting depth of an HS formula  $\psi$  (Nest<sub>BF</sub>( $\psi$ )) is the maximum degree of nesting of modalities B and E in  $\psi$
- ▶ Two traces  $\rho$  and  $\rho'$  of a Kripke structure  $\mathcal{K}$  are k-equivalent if and only if  $\mathcal{K}, \rho \models \psi$  iff  $\mathcal{K}, \rho' \models \psi$  for all HS-formulas  $\psi$  with  $Nest_{BF}(\psi) \leq k$

## Model checking: the key notion of $BE_k$ -descriptor

- ▶ The BE-nesting depth of an HS formula  $\psi$  (Nest<sub>BE</sub>( $\psi$ )) is the maximum degree of nesting of modalities B and E in  $\psi$
- ▶ Two traces  $\rho$  and  $\rho'$  of a Kripke structure  $\mathcal K$  are k-equivalent if and only if  $\mathcal K$ ,  $\rho \models \psi$  iff  $\mathcal K$ ,  $\rho' \models \psi$  for all HS-formulas  $\psi$  with Nest<sub>BE</sub> $(\psi) \le k$

For any given k, we provide a suitable tree representation for a trace, called a  $BE_k$ -descriptor

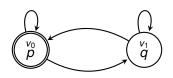

The  $BE_k$ -descriptor for a trace  $\rho = v_0v_1...v_{m-1} v_m$ , denoted  $BE_k(\rho)$ , has the following structure:

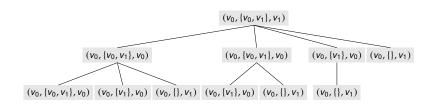

Remark: the descriptor does not feature sibling isomorphic subtrees

Angelo Monte

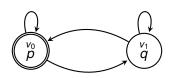

## An example of a BE<sub>2</sub>-descriptor

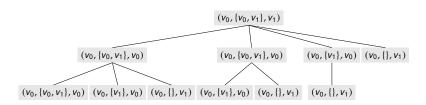

The  $BE_2$ -descriptor for the trace  $\rho = v_0v_1v_0^4v_1$  (for the sake of readability, only the subtrees for prefixes are displayed and point intervals are excluded)

## An example of a BE<sub>2</sub>-descriptor

The BE<sub>2</sub>-descriptor for the trace  $\rho = v_0 v_1 v_0^4 v_1$  (for the sake of readability, only the subtrees for prefixes are displayed and point intervals are excluded)

Remark: the subtree to the left is associated with both prefixes  $v_0v_1v_0^3$  and  $v_0v_1v_0^4$  (no sibling isomorphic subtrees in the descriptor)

4 D F 4 B F 4 B F 4 B F

FACT 1: For any Kripke structure K and any BE-nesting depth  $k \geq 0$ , the number of different  $BE_k$ -descriptors is finite (and thus at least one descriptor has to be associated with infinitely many traces)

FACT 1: For any Kripke structure  $\mathcal{K}$  and any BE-nesting depth  $k \geq 0$ , the number of different  $BE_k$ -descriptors is finite (and thus at least one descriptor has to be associated with infinitely many traces)

**FACT 2**: Two traces  $\rho$  and  $\rho'$  of a Kripke structure  $\mathcal{K}$  described by the same  $BE_k$  descriptor are k-equivalent

FACT 1: For any Kripke structure  $\mathcal{K}$  and any BE-nesting depth  $k \geq 0$ , the number of different  $BE_k$ -descriptors is finite (and thus at least one descriptor has to be associated with infinitely many traces)

**FACT 2**: Two traces  $\rho$  and  $\rho'$  of a Kripke structure  $\mathcal{K}$  described by the same  $BE_k$  descriptor are k-equivalent

#### Theorem

The model checking problem for full HS on finite Kripke structures is decidable (with a non-elementary algorithm)

A. Molinari, A. Montanari, A. Murano, G. Perelli, and A. Peron, Checking Interval Properties of Computations, Acta Informatica, Special Issue: Temporal Representation and Reasoning (TIME'14), Vol. 56, n. 6-8, October 2016, pp. 587-619

FACT 1: For any Kripke structure  $\mathcal{K}$  and any BE-nesting depth  $k \geq 0$ , the number of different  $BE_k$ -descriptors is finite (and thus at least one descriptor has to be associated with infinitely many traces)

**FACT 2**: Two traces  $\rho$  and  $\rho'$  of a Kripke structure  $\mathcal{K}$  described by the same  $BE_k$  descriptor are k-equivalent

#### Theorem

The model checking problem for full HS on finite Kripke structures is decidable (with a non-elementary algorithm)

A. Molinari, A. Montanari, A. Murano, G. Perelli, and A. Peron, Checking Interval Properties of Computations, Acta Informatica, Special Issue: Temporal Representation and Reasoning (TIME'14), Vol. 56, n. 6-8, October 2016, pp. 587-619

What about lower bounds?

## The logic BE

#### Theorem

The model checking problem for BE, over finite Kripke structures, is EXPSPACE-hard

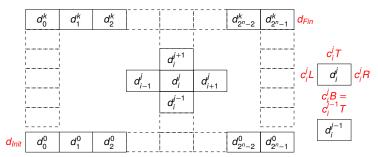

L. Bozzelli, A. Molinari, A. Montanari, A. Peron, and P. Sala, Interval Temporal Logic Model Checking: The Border Between Good and Bad HS Fragments, IJCAR 2016

Proof: a polynomial-time reduction from a domino-tiling problem for grids with rows of single exponential length

- for an instance I of the problem, we build a Kripke structure  $K_I$  and a BE formula  $\varphi_{\mathcal{I}}$  in polynomial time
- there is an initial trace of  $K_I$  satisfying  $\varphi_I$  iff there is a tiling of I
- $\mathcal{K}_{\mathcal{I}} \models \neg \varphi_{\mathcal{I}}$  iff there exists no tiling of  $\mathcal{I}$

## BE hardness: encoding of the domino-tiling problem

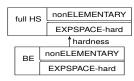

Instance of the tiling problem:  $(C, \Delta, n, d_{init}, d_{final})$ , with C a finite set of colors and  $\Delta \subseteq C \times C \times C \times C$  a set of tuples  $(c_R, c_L, c_T, c_R)$ 

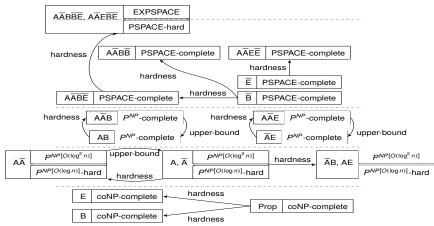

#### String (interval) encoding of the problem

Model Checking: the Interval Way

◆□ → ◆同 → ◆三 → ◆同 → ◆同 → ◆回 →

Angelo Montanari

## Three main gaps to fill

#### There are three main gaps to fill:

- full HS and BE are in between nonELEMENTARY and **EXPSPACE**
- ► AABBE, AAEBE, ABBE, AEBE, ABBE, and AEBE are in between EXPSPACE and PSPACE
- ► A, A,  $\overrightarrow{AA}$ ,  $\overrightarrow{AB}$ , and  $\overrightarrow{AE}$  are in between  $P^{NP[O(\log^2 n)]}$  and  $PNP[O(\log n)]$

Let us consider the case of the logic  $\overline{AABBE}$ , which is obtained from full HS ( $\overline{AABBEE}$ ) by removing modality  $\langle E \rangle$ 

Let us consider the case of the logic AABBE, which is obtained from full HS (AABBEE) by removing modality (E)

A high-level account of the solution:

• we can restrict our attention to prefixes ( $B_k$ -descriptors suffice)

Let us consider the case of the logic AABBE, which is obtained from full HS (AABBEE) by removing modality (E)

A high-level account of the solution:

- we can restrict our attention to prefixes  $(B_k$ -descriptors suffice)
- the size of the tree representation of B<sub>k</sub>-descriptors is larger than necessary (redundancy) and it prevents their efficient exploitation in model checking algorithms

Let us consider the case of the logic AABBE, which is obtained from full HS (AABBEE) by removing modality (E)

A high-level account of the solution:

- we can restrict our attention to prefixes  $(B_k$ -descriptors suffice)
- the size of the tree representation of  $B_k$ -descriptors is larger than necessary (redundancy) and it prevents their efficient exploitation in model checking algorithms
- a trace representative can be chosen to represent a (possibly infinite) set of traces with the same  $B_k$ -descriptor

Let us consider the case of the logic  $\overline{AABBE}$ , which is obtained from full HS  $(\overline{AABBEE})$  by removing modality  $\langle E \rangle$ 

#### A high-level account of the solution:

- we can restrict our attention to prefixes ( $B_k$ -descriptors suffice)
- the size of the tree representation of  $B_k$ -descriptors is larger than necessary (redundancy) and it prevents their efficient exploitation in model checking algorithms
- a trace representative can be chosen to represent a (possibly infinite) set of traces with the same B<sub>κ</sub>-descriptor
- a bound, which depends on both the number |W| of states of the Kripke structure and the B-nesting depth h of the formula to check, can be given to the length of trace representatives

## The key notion: prefix-bisimilarity

#### Definition (Prefix-bisimilarity)

Two traces  $\rho$  and  $\rho'$  are h-prefix bisimilar if the following conditions inductively hold:

- for h = 0:  $fst(\rho) = fst(\rho')$ ,  $lst(\rho) = lst(\rho')$ , and  $states(\rho) = states(\rho')$
- for h > 0:  $\rho$  and  $\rho'$  are 0-prefix bisimilar and for each proper prefix  $\nu$  of  $\rho$  (resp.,  $\nu'$  of  $\rho'$ ), there exists a proper prefix  $\nu'$  of  $\rho'$  (resp.,  $\nu$  of  $\rho$ ) such that  $\nu$  and  $\nu'$  are (h-1)-prefix bisimilar

Notice that: (i) h-prefix bisimilarity is an equivalence relation over traces, and (ii) h-prefix bisimilarity propagates downwards

### The key notion: prefix-bisimilarity

#### Definition (Prefix-bisimilarity)

Two traces  $\rho$  and  $\rho'$  are h-prefix bisimilar if the following conditions inductively hold:

- ▶ for h = 0: fst( $\rho$ ) = fst( $\rho'$ ), lst( $\rho$ ) = lst( $\rho'$ ), and states( $\rho$ ) = states( $\rho'$ )
- for h > 0: ρ and ρ' are 0-prefix bisimilar and for each proper prefix ν of ρ (resp., ν' of ρ'), there exists a proper prefix ν' of ρ' (resp., ν of ρ) such that ν and ν' are (h - 1)-prefix bisimilar

Notice that: (i) *h*-prefix bisimilarity is an equivalence relation over traces, and (ii) *h*-prefix bisimilarity propagates downwards

#### Proposition

Let  $h \ge 0$ , and  $\rho$ ,  $\rho'$  be two h-prefix bisimilar traces of a Kripke structure  $\mathcal{K}$ . For each  $A\overline{A}B\overline{BE}$  formula  $\psi$ , with  $Nest_B(\psi) \le h$ , it holds that  $\mathcal{K}$ ,  $\rho \models \psi \iff \mathcal{K}$ ,  $\rho' \models \psi$ 

Alger montain

## An EXPSPACE model checking algorithm for AABBE

#### Theorem (Small model/trace property)

Given a trace  $\rho$ , we can derive a trace  $\rho'$ , induced by  $\rho$  and h-prefix bisimilar to it, such that  $|\rho'| \leq (|W| + 2)^{h+2}$ 

L. Bozzelli, A. Molinari, A. Montanari, A. Peron, and P. Sala, Interval Temporal Logic Model Checking Based on Track Bisimilarity and Prefix Sampling, Proceedings of the 17th Italian Conference on Theoretical Computer Science (ICTCS), CEUR, September 2016, pp. 49-61

#### Algorithm 1 ModCheck( $\mathcal{K}, \psi$ )

- 1:  $h \leftarrow \text{Nest}_{\mathsf{R}}(\psi)$
- 2:  $u \leftarrow New (Unravelling(\mathcal{K}, w_0, h))$

 $\triangleleft w_{\cap}$  initial state of  $\mathcal{K}$ 

- 3: while u.hasMoreTracks() do
- $\rho' \leftarrow u.getNextTrack()$
- 5: if  $Check(\mathcal{K}, h, \psi, \rho') = 0$  then return 0: " $\mathcal{K}, \rho' \not\models \psi$ "  $\triangleleft$  Counterexample found  $\mathcal{X}$ return 1: " $\mathcal{K} \models \psi$ "

## PSPACE-hardness of AABBE model checking

PSPACE-hardness of the model checking problem for B (and thus for AABBE) can be proved by a reduction from the QBF problem

#### Theorem

The model checking problem for B, and thus for AABBE, over finite Kripke structures is PSPACE-hard

A. Molinari, A. Montanari, A. Peron, and P. Sala, Model Checking Well-Behaved Fragments of HS: The (Almost) Final Picture, KR 2016

AABBE model checking is thus in between PSPACE and EXPSPACE (remind: BE model checking is EXPSPACE-hard)

### Point vs. interval temporal logic model checking

Question: is there any advantage in replacing points by intervals as the primary temporal entities, or is it just a matter of taste?

In order to compare the expressiveness of HS in model checking with those of LTL, CTL, and CTL\*, we consider three semantic variants of HS:

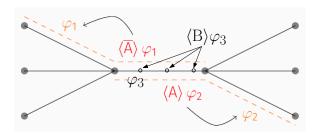

- ► HS with state-based semantics (the original one)
- HS with computation-tree-based semantics
- HS with trace-based semantics

These variants are compared with the above-mentioned standard temporal logics and among themselves

L. Bozzelli, A. Molinari, A. Montanari, A. Peron, and P. Sala, Interval vs. Point Temporal Logic Model Checking: an Expressiveness Comparison. Proceedings of the 36th IARCS Annual Conference on Foundations of Software Technology and Theoretical Computer Science (FSTTCS), December 2016, pp. 26:1-14

#### Branching semantic variant of HS

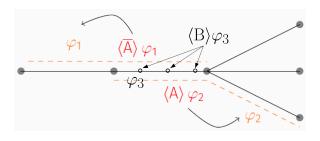

#### State-based semantics of HS (HS<sub>st</sub>):

both the future and the past are branching

A. Molinari, A. Montanari, A. Murano, G. Perelli, and A. Peron, Checking Interval Properties of Computations, Acta Informatica, Special Issue: Temporal Representation and Reasoning (TIME'14), Vol. 56, n. 6-8, October 2016, pp. 587-619

#### Linear-past semantic variant of HS

#### Computation-tree-based semantics of HS (HS<sub>ct</sub>):

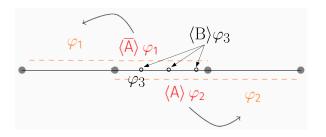

- the future is branching
- the past is linear, finite and cumulative
- similar to CTL\* + linear past

A. Lomuscio and J. Michaliszyn, Decidability of model checking multi-agent systems against a class of EHS specifications, Proc. of the 21st European Conference on Artificial Intelligence (ECAI), August 2014, pp. 543–548

Model Checking: the Interval Way Angelo Montan

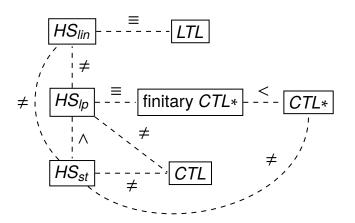

#### Linear semantic variant of HS

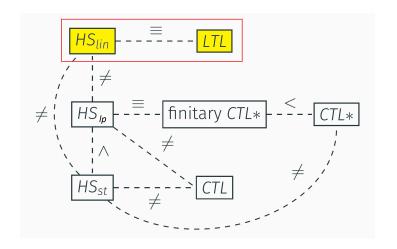

#### Trace-based semantics of HS (HS<sub>lin</sub>):

- neither the past not the future is branching
- similar to LTL + past

### The expressiveness picture

# Equivalence between LTL and HS<sub>lin</sub>

#### Equivalence between LTL and HS<sub>lin</sub>: LTL and FO

**FO** formulas  $\varphi$  (first-order fragment of MSO over infinite words):

$$\varphi := \top \mid p \in x \mid x \le y \mid x < y \mid \neg \varphi \mid \varphi \land \varphi \mid \exists x. \varphi$$

- we interpret FO formulas  $\varphi$  over infinite paths  $\pi$  of Kripke structures
- ightharpoonup a valuation function g assigns to each variable a position  $i \geq 0$
- the satisfaction relation  $(\pi, g) \models \varphi$  corresponds to the standard satisfaction relation  $(\mu(\pi), g) \models \varphi$ , where  $\mu(\pi)$  is the infinite word over  $2^{\mathcal{AP}}$  given by  $\mu(\pi(0))\mu(\pi(1))\cdots$

#### Equivalence between LTL and HS<sub>lin</sub>: LTL and FO

**FO** formulas  $\varphi$  (first-order fragment of MSO over infinite words):

$$\varphi := \top \mid p \in x \mid x \le y \mid x < y \mid \neg \varphi \mid \varphi \land \varphi \mid \exists x. \varphi$$

- we interpret FO formulas  $\varphi$  over infinite paths  $\pi$  of Kripke structures
- ightharpoonup a valuation function g assigns to each variable a position  $i \geq 0$
- the satisfaction relation  $(\pi, g) \models \varphi$  corresponds to the standard satisfaction relation  $(\mu(\pi), g) \models \varphi$ , where  $\mu(\pi)$  is the infinite word over  $2^{\mathcal{AP}}$  given by  $\mu(\pi(0))\mu(\pi(1))\cdots$

#### Theorem (Kamp's theorem)

Given a FO sentence  $\varphi$  over AP, one can construct an LTL formula  $\psi$  such that for all Kripke structures K over AP and infinite paths  $\pi$ ,

$$\pi \models \varphi \iff \pi, 0 \models \psi$$

# Equivalence between LTL and HS<sub>lin</sub>: LTL ≥ HS<sub>lin</sub>

Given an HS<sub>lin</sub> formula  $\psi$ , one can build an FO sentence  $\psi_{\text{FO}}$  such that, for all Kripke structures  $\mathcal{K}$ , it holds that

 $\mathcal{K}\models_{\mathsf{lin}}\psi$  iff for each initial infinite path  $\pi$  of  $\mathcal{K}$ ,  $\mathcal{K}$ ,  $\pi\models\psi_{\mathsf{FO}}$ 

$$\psi_{\mathsf{FO}} = \exists x ((\forall z.z \geq x) \land \forall y.h(\psi,x,y))$$

$$\begin{array}{ll} h(p,x,y) &= \forall z. ((z \geq x \land z \leq y) \to p \in z) \\ h(\langle E \rangle \psi, x, y) &= \exists z. (z > x \land z \leq y \land h(\psi, z, y)) \\ h(\langle B \rangle \psi, x, y) &= \exists z. (z \geq x \land z < y \land h(\psi, x, z)) \\ h(\langle \overline{E} \rangle \psi, x, y) &= \exists z. (z < x \land h(\psi, z, y)) \\ h(\langle \overline{B} \rangle \psi, x, y) &= \exists z. (z > y \land h(\psi, x, z)) \end{array}$$

# Theorem $LTL \ge HS_{lin}$

4 D > 4 D > 4 E > 4 E > E 9 Q C

### Equivalence between LTL and HS<sub>lin</sub>: HS<sub>lin</sub> ≥ LTL

The converse containment holds as well ( $HS_{lin} \ge LTL$ )

#### **Theorem**

Given an LTL formula  $\varphi$ , we can construct in linear time an AB formula  $\psi$  such that  $\varphi$  in LTL is equivalent to  $\psi$  in AB<sub>lin</sub>

$$\begin{split} f(p) &= p, \text{ for each proposition letter } p \\ f(\mathsf{X}\psi) &= \langle \mathsf{A} \rangle (\mathit{length}_2 \wedge \langle \mathsf{A} \rangle (\mathit{length}_1 \wedge f(\psi))), \\ f(\psi_1 \mathsf{U}\psi_2) &= \langle \mathsf{A} \rangle \Big( \langle \mathsf{A} \rangle (\mathit{length}_1 \wedge f(\psi_2)) \wedge [B] (\langle \mathsf{A} \rangle (\mathit{length}_1 \wedge f(\psi_1)) \Big) \end{split}$$

It holds that  $\mathcal{K} \models \psi$  iff  $\mathcal{K} \models_{lin} length_1 \rightarrow f(\psi)$ 

#### Corollary

HS<sub>lin</sub> and LTL have the same expressive power

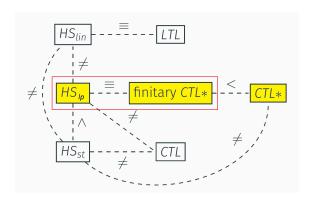

#### What about succinctness?

Things change if we consider succinctness: while it is possible to convert any LTL formula into an equivalent HS<sub>lin</sub> one in linear time, HS<sub>lin</sub> is at least exponentially more succinct than LTL

To prove it, it suffices to provide an HS<sub>lin</sub> formula  $\psi$  for which there exists no LTL equivalent formula whose size is polynomial in  $|\psi|$ 

We restrict our attention to the fragment BE<sub>lin</sub>: since modalities (B) and  $\langle E \rangle$  only allow one to 'move' from an interval to its subintervals, BE<sub>lin</sub> actually coincides with BE<sub>st</sub>, whose MC is known to be hard for FXPSPACE

## A characterization of HSct

# A characterization of $HS_{ct}$ : $HS_{ct} \ge finitary CTL^* - 1$

We first show that finitary CTL\* is subsumed by HS<sub>ct</sub> (finitary CTL\* = path quantification ranges over the traces starting from the current state)

Preliminary step: when interpreted over finite words, the BE fragment of HS and LTL define the same class of finitary languages

Action-based semantics of BE ( $L_{act}(\varphi)$ ):

- $L_{act}(a) = a^+$  for each  $a \in \Sigma$ ;
- $L_{act}(\neg \varphi) = \Sigma^+ \setminus L_{act}(\varphi);$
- ►  $L_{act}(\varphi_1 \wedge \varphi_2) = L_{act}(\varphi_1) \cap L_{act}(\varphi_2)$ ;
- ►  $L_{act}(\langle \mathsf{B} \rangle \varphi) = \{ \mathsf{w} \in \Sigma^+ \mid \mathsf{Pref}(\mathsf{w}) \cap L_{act}(\varphi) \neq \emptyset \};$
- ►  $L_{act}(\langle \mathsf{E} \rangle \varphi) = \{ \mathsf{w} \in \Sigma^+ \mid \mathsf{Suff}(\mathsf{w}) \cap L_{act}(\varphi) \neq \emptyset \}.$

Easy direction: over finite words, the class of languages defined by BE is subsumed by that defined by LTL

#### A characterization of HS<sub>ct</sub>: HS<sub>ct</sub> ≥ finitary CTL\* - 2

Converse direction: we exploit a sufficient condition for the inclusion of the class of LTL-definable languages, called LTL-closure, stating that any LTL-closed class C of finitary languages includes the class of LTL-definable finitary languages (Wilke)

### A characterization of $HS_{ct}$ : $HS_{ct} \geq finitary CTL^* - 2$

Converse direction: we exploit a sufficient condition for the inclusion of the class of LTL-definable languages, called LTL-closure, stating that any LTL-closed class C of finitary languages includes the class of LTL-definable finitary languages (Wilke)

#### Proposition

Let  $\varphi$  be an LTL formula over a finite alphabet  $\Sigma$ . Then, there exists a BE formula  $\varphi_{HS}$  over  $\Sigma$  such that  $L_{act}(\varphi_{HS}) = L_{act}(\varphi)$ 

Proof: the class of BE-definable finitary languages is LTL-closed

### A characterization of $HS_{ct}$ : $HS_{ct} \geq finitary CTL^* - 2$

Converse direction: we exploit a sufficient condition for the inclusion of the class of LTL-definable languages, called LTL-closure, stating that any LTL-closed class C of finitary languages includes the class of LTL-definable finitary languages (Wilke)

#### Proposition

Let  $\varphi$  be an LTL formula over a finite alphabet  $\Sigma$ . Then, there exists a BE formula  $\varphi_{HS}$  over  $\Sigma$  such that  $L_{act}(\varphi_{HS}) = L_{act}(\varphi)$ 

Proof: the class of BE-definable finitary languages is LTL-closed

#### Theorem

Let  $\varphi$  be a finitary CTL\* formula over  $\mathcal{AP}$ . Then, there is an ABE formula  $\varphi_{HS}$  over  $\mathcal{AP}$  such that for all Kripke structures  $\mathcal{K}$  over  $\mathcal{AP}$ and tracks  $\rho$ ,  $\mathcal{K}$ ,  $\rho$ ,  $0 \models \varphi$  iff  $\mathcal{K}$ ,  $\rho \models_{st} \varphi_{HS}$ .

### A characterization of $HS_{ct}$ : $HS_{ct} \geq finitary CTL^* - 2$

Converse direction: we exploit a sufficient condition for the inclusion of the class of LTL-definable languages, called LTL-closure, stating that any LTL-closed class C of finitary languages includes the class of LTL-definable finitary languages (Wilke)

#### Proposition

Let  $\varphi$  be an LTL formula over a finite alphabet  $\Sigma$ . Then, there exists a BE formula  $\varphi_{HS}$  over  $\Sigma$  such that  $L_{act}(\varphi_{HS}) = L_{act}(\varphi)$ 

Proof: the class of BE-definable finitary languages is LTL-closed

#### **Theorem**

Let  $\varphi$  be a finitary CTL\* formula over  $\mathcal{AP}$ . Then, there is an ABE formula  $\varphi_{HS}$  over  $\mathcal{AP}$  such that for all Kripke structures  $\mathcal{K}$  over  $\mathcal{AP}$ and tracks  $\rho$ ,  $\mathcal{K}$ ,  $\rho$ ,  $0 \models \varphi$  iff  $\mathcal{K}$ ,  $\rho \models_{st} \varphi_{HS}$ .

Since for ABE the computation-tree-based and the state-based semantics coincide, the following corollary holds:

both  $HS_{st} \ge finitary CTL^*$  and  $HS_{ct} \ge finitary CTL^*$ 

4 D > 4 P > 4 B > 4 B >

# A characterization of $HS_{ct}$ : (finitary) $CTL^* \ge HS_{ct}$ - 1

Then, we show that HS<sub>ct</sub> is subsumed by finitary CTL\* and CTL\*

# A characterization of HS<sub>ct</sub>: (finitary) CTL\* ≥ HS<sub>ct</sub> - 1

Then, we show that HS<sub>ct</sub> is subsumed by finitary CTL\* and CTL\* Hybrid CTL\* $_{|p}$  (hybrid and linear past extension of CTL\*):  $\varphi := \top \mid p \mid x \mid \neg \varphi \mid \varphi \lor \varphi \mid \downarrow x. \varphi \mid X\varphi \mid \varphi U\varphi \mid X^{-}\varphi \mid \varphi U^{-}\varphi \mid \exists \varphi$ 

- $\blacktriangleright \pi, g, i \models x \Leftrightarrow g(x) = i$
- $\qquad \qquad \pi, g, i \models \downarrow x. \varphi \Leftrightarrow \pi, g[x \leftarrow i], i \models \varphi$
- path quantification is "memoryful": it ranges over infinite paths that start at the root and visit the current node of the computation tree.

# A characterization of $HS_{ct}$ : (finitary) $CTL^* \geq HS_{ct}$ - 1

Then, we show that HS<sub>ct</sub> is subsumed by finitary CTL\* and CTL\* Hybrid CTL<sub>in</sub> (hybrid and linear past extension of CTL\*):  $\varphi ::= \top | p | x | \neg \varphi | \varphi \lor \varphi | \downarrow x.\varphi | X\varphi | \varphi U\varphi | X^-\varphi | \varphi U^-\varphi | \exists \varphi$ 

- $\blacktriangleright \pi, g, i \models x \Leftrightarrow g(x) = i$
- path quantification is "memoryful": it ranges over infinite paths that start at the root and visit the current node of the computation tree.

#### Well-formed hybrid $CTL_{ln}^*$ :

- lacktriangle each subformula  $\exists \psi$  has at most one free variable
- each subformula  $\exists \psi(x)$  of  $\varphi$  having x as free variable occurs in  $\varphi$  in the context  $(F^-x) \wedge \exists \psi(x)$

Intuitively, for each state subformula  $\exists \psi$ , the unique free variable (if any) refers to ancestors of the current node in the computation tree

# A characterization of $HS_{ct}$ : (finitary) $CTL^* \ge HS_{ct} - 2$

#### Proposition

Given a  $HS_{\rm ct}$  formula  $\varphi$ , one can construct an equivalent well-formed sentence of hybrid  $CTL_{lp}^*$  (resp., finitary hybrid  $CTL_{lp}^*$ ) (Not that difficult)

# A characterization of $HS_{ct}$ : (finitary) $CTL^* \geq HS_{ct} - 2$

#### Proposition

Given a  $HS_{ct}$  formula  $\varphi$ , one can construct an equivalent well-formed sentence of hybrid CTL\* (resp., finitary hybrid CTL\*) (Not that difficult)

#### Proposition

Well-formed hybrid  $CTL_{lo}^*$  (resp., finitary hybrid  $CTL_{lo}^*$ ) has the same expressiveness as CTL\* (resp., finitary CTL\*)

(Difficult!—It exploits the separation theorem for LTL + past)

# A characterization of $HS_{ct}$ : (finitary) $CTL^* \geq HS_{ct} - 2$

#### Proposition

Given a  $HS_{ct}$  formula  $\varphi$ , one can construct an equivalent well-formed sentence of hybrid CTL\* (resp., finitary hybrid CTL\*) (Not that difficult)

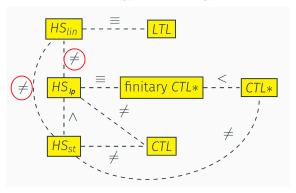

#### Proposition

Well-formed hybrid  $CTL_{lp}^*$  (resp., finitary hybrid  $CTL_{lp}^*$ ) has the same expressiveness as CTL\* (resp., finitary CTL\*) (Difficult!—It exploits the separation theorem for LTL + past)

#### Theorem

 $CTL^* \geq HS_{ct}$ . Moreover,  $HS_{ct}$  is as expressive as finitary  $CTL^*$ 

### A comparison of HS<sub>lin</sub>, HS<sub>ct</sub>, and HS<sub>st</sub> - 1

- ► The reachability condition  $\forall G \exists Fp$  (from each state reachable from the initial one, it is possible to reach a state where p holds) is not LTL-definable, but it is easily definable in  $HS_{ct}$  and  $HS_{st}$  by the formula  $\langle \overline{B} \rangle \langle E \rangle p$
- ► The LTL formula Fp cannot be expressed in HS<sub>ct</sub> or HS<sub>st</sub> (Not immediate!)

# A comparison of HS<sub>lin</sub>, HS<sub>ct</sub>, and HS<sub>st</sub> - 2

- We have already proved that CTL\* ≥ HS<sub>ct</sub>, HS<sub>st</sub> ≥ HS<sub>ct</sub>
- ► HS<sub>ct</sub>, CTL, CTL\* are not sensitive to unwinding, HS<sub>st</sub> is
- ► The CTL formula ∀Fp cannot be expressed in HS<sub>ct</sub> or HS<sub>st</sub>
- ► The finitary CTL\* formula  $\exists (((p_1 U p_2) \lor (q_1 U q_2)) U r)$  cannot be expressed in CTL

### ITL model checking with regular expressions

Can we relaxe the homogeneity assumption? The addition of regular expressions:

$$r ::= \varepsilon \mid \phi \mid r \cup r \mid r \cdot r \mid r^*$$

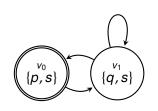

where  $\phi$  is a Boolean (propositional) formula over  $\mathcal{AP}$ .

#### Examples:

$$r_1 = (\mathbf{p} \wedge \mathbf{s}) \cdot \mathbf{s}^* \cdot (\mathbf{p} \wedge \mathbf{s})$$

► 
$$r_2 = (\neg \mathbf{p})^*$$

- $\mu(\rho) = \{p, s\}\{q, s\}\{p, s\}\{q, s\}\{q, s\}$
- $\rho' = v_0 v_1 v_1 v_1 v_0$
- $\mu(\rho') = \{p, s\}\{q, s\}\{q, s\}\{q, s\}\{p, s\}$ 
  - $\mu(\rho) \notin (r_1)$ , but  $\mu(\rho') \in (r_1)$
  - $\mu(\rho) \notin (r_2)$  and  $\mu(\rho') \notin (r_2)$

# ITL model checking with regular expressions

In the definition of the truth of a formula  $\psi$  over a trace  $\rho$  of a Kripke structure  $\mathcal{K} = (\mathcal{AP}, W, \delta, \mu, w_0)$ , we replace the clause for propositional letters by a clause for regular expressions:

• 
$$\mathcal{K}$$
,  $\rho \models r$  iff  $\mu(\rho) \in \mathcal{L}(r)$ 

Homogeneity can be recovered as a special case. To force it, all regular expressions in the formula must be of the form:

$$p \cdot (p)^*$$

Solution: given K and an HS formula  $\varphi$  over AP, we build an NFA over  $\mathcal{K}$  accepting the set of traces  $\rho$  such that  $\mathcal{K}$ ,  $\rho \models \varphi$ .

#### ITL model checking with regular expressions

Model checking for full HS with regular expressions is decidable and its complexity, when restricted to system models—that is, if we assume the formula to be constant length—is PTIME

Model checking for AABB and its fragments is PSPACE-complete

L. Bozzelli, A. Molinari, A. Montanari, and A. Peron, An In-Depth Investigation of Interval Temporal Logic Model Checking with Regular Expressions. Proc. of the 15th International Conference on Software Engineering and Formal Methods (SEFM), LNCS 10469, Springer, September 2017, pp. 104-119

Model checking for AABBE and AAEBE with regular expressions is AEXP<sub>pol</sub>-complete ( AEXP<sub>pol</sub> is the complexity class of problems decided by exponential-time bounded alternating Turing Machines with a polynomially bounded number of alternations)

L. Bozzelli, A. Molinari, A. Montanari, and A. Peron, On the Complexity of Model Checking for Syntactically Maximal Fragments of the Interval Temporal Logic HS with Regular Expressions. Proc. of the 8th International Symposium on Games, Automata, Logics and Formal Verification (GandALF), EPTCS 256, September 2017, pp. 31-45

### Ongoing work and future developments - 1

Ongoing work: to determine the exact complexity of the satisfiability / model checking problems for BE over finite linear orders, under the homogeneity assumption (the three semantic variants of HS coincide over BE)

We know that the satisfiability/model checking problems for D over finite linear orders, under the homogeneity assumption, are PSPACE-complete (we exploit a spatial encoding of the models for D and a suitable contraction technique)

L. Bozzelli, A. Molinari, A. Montanari, A. Peron, and P. Sala, Satisfiability and Model Checking for the Logic of Sub-Intervals under the Homogeneity Assumption, Proc. of the 44th International Colloquium on Automata, Languages, and Programming(ICALP), LIPIcs 80, July 2017, pp. 120:1-120:14

There is no a natural way to generalize the solution for D to BE

4 D > 4 P > 4 B > 4 B >

# Ongoing work and future developments - 2

As for future developments, we are looking for possible replacements of Kripke structures by more expressive system models

- visibly pushdown systems, that can encode recursive programs and infinite state systems
- inherently interval-based models, that allows one to directly describe systems on the basis of their interval behavior/properties, such as, for instance, those involving actions with duration, accomplishments, or temporal aggregations (no restriction on the evaluation of proposition letters)

Application: planning as satisfiability checking / model checking in interval temporal logic
