Abstract

Invariance of interpretation by β -conversion is one of the minimal requirements for any standard model for the λ -calculus. With the intersection type systems being a general framework for the study of semantic domains for the λ -calculus, the present paper provides a (syntactic) characterisation of the above mentioned requirement in terms of characterisation results for intersection type assignment systems.

Instead of considering conversion as a whole, reduction and expansion will be considered separately. Not only for usual computational rules like β , η , but also for a number of relevant restrictions of those. Characterisations will be also provided for (intersection) filter structures that are indeed λ -models.

1 Introduction

In the λ -calculus, the computational model at the basis of the functional programming paradigm, the basic step of computation is usually identified with the notion

of β -reduction:

$$(\lambda x.M)N \rightarrow_{\beta} M[x := N]$$

Whereas, like any “computation rule”, its role is (roughly) to make more *explicit* the “information” represented by a λ -term, such information, intuitively, must not be modified by the computational process embodied by the rule itself. That is why any classical notion of denotational interpretation for the λ -calculus has to respect minimal requisites w.r.t. the operational interpretation of the calculus. As a matter of fact, any classical denotational semantics for the λ -calculus must be required *sound*, that is it must interpret any two *convertible* terms with the very same information (denotational value).

The soundness requirement for denotational models for the λ -calculus is, at large, the context of the present paper. In particular, we address the study of this requirement at a deeper level, that is, we “decompose” it into two separate requirements to be investigated individually: one concerning β -reduction alone and one concerning β -expansion.

$$(a) \quad \text{For any } N \text{ s.t. } M \rightarrow_{\beta} N, \quad \llbracket M \rrbracket = \llbracket N \rrbracket$$

$$(b) \quad \text{For any } N \text{ s.t. } N \rightarrow_{\beta} M, \quad \llbracket M \rrbracket = \llbracket N \rrbracket$$

where $\llbracket M \rrbracket$ represents the denotational interpretation of the term M in a given domain.

Due to the large variety of possible denotational models for the λ -calculus, such an investigation cannot be successfully undertaken unless we manage to identify a finitary and natural framework where most of the models proposed in the literature could be “embedded” and analysed.

Type assignment systems for the untyped λ -calculus with intersection types are definitely a framework with the qualities we are looking for: they form a class of type assignment systems which allow to express, in a natural and finitary way, many of the most important *denotational* properties of terms (as a matter of fact, also many relevant *operational* properties can be characterised by means of intersection types).

Indeed, intersection types are a powerful tool for both the analysis and synthesis of λ -models (see *e.g.* [9] [11], [18], [24], [23], [28], [15], [6] and the references there): on the one hand, intersection type disciplines provide finitary inductive definitions of interpretation of λ -terms in models. On the other hand, they are suggestive for the shape the domain model has to have in order to exhibit certain properties (see *e.g.* [11], [24], [5], [7], [17], [14]).

Intersection types can be also viewed as a restriction of the domain theory in logical form, see [1], to the special case of modelling pure λ -calculus by means of ω -algebraic complete lattices. Many properties of these models can be proved using this paradigm, which goes back to Stone duality.

Different finitary characterisations of models for the λ -calculus can be obtained by introducing specific constants, typing rules and type preorders in the basic intersection type assignment system. An element of a particular domain, representing the denotational meaning of a term M , comes out to correspond to the set of types that can be inferred for M .

It is then clear that, in the framework of intersection type systems, the study of the requirements (a) and (b) above mentioned can be fully formalised in terms of *typing invariance*, that is, in type theory terminology, by the so-called Subject Reduction and Expansion properties. Hence, particular (syntactic) characterisations of those domains where the requirement (a) (resp. (b)) is met, can be achieved by isolating necessary and sufficient conditions enabling a type system to enjoy the property of Subject Reduction (resp. Subject Expansion). One of the main results of the present paper consists in a number of such necessary and sufficient conditions for these properties.

It is worth noticing that many restrictions of the β -rule have been devised in the literature with the aim of formalising particular sorts of computations. Interesting examples of such restrictions are the rule of Plotkin's λ_v -calculus [27], the rule of $\lambda\mathbf{I}$ -calculus [13] and the rule of $\lambda\mathbf{KN}$ -calculus [23]. In this paper we shall prove our results also for the restricted notions of computations embodied by the above mentioned calculi.

β -conversion as a whole will be also taken into account in this paper, but from a rather broader perspective (forming the basis for further research): characterisation results will be in fact provided for those filter (intersection) structures that are also λ -models for the afore mentioned calculi. Such results will profit from the characterisation results concerning Subject Reduction and Subject Expansion.

The extensionality property in the denotational semantics for the λ -calculus will be taken into account in terms of its syntactic formalization: the η -rule. We shall show how to characterise the intersection type systems enjoying Subject Reduction and Subject Expansion properties with respect to η -rule, as well as the filter structures that are extensional λ -models for the considered calculi.

This paper is structured as follows: in Section 2 we recall the definitions of intersection types and intersection type preorders. We shall briefly recall the main systems proposed in the literature, in particular those related to the use of intersection types for denotational semantics. We shall also introduce conditions on type preorders to be used in our characterisation results. Section 3 discusses intersection type assignment systems and their properties. Section 4 will contain our characterisation results concerning β - and η -reduction/expansion. Our characterisations of filter structure that are λ -models will be given in Section 5. The last section (Section 6) will provide a few remarks on possible further research on the arguments of the paper.

The present paper extends [3] and [4] providing all the omitted proofs in those preliminary versions.

2 Intersection Type Languages and Type Preorders

In this section we shall recall the main notions concerning intersection type languages and type preorders.

Intersection types are syntactic objects built by closing a given set \mathbb{C} of *type atoms* (constants) under the *function type* constructor \rightarrow , and the *intersection type* constructor \cap .

Definition 1 (Intersection Type Language) *The intersection type language over \mathbb{C} , denoted by $\mathbb{T} = \mathbb{T}(\mathbb{C})$ is defined by the following abstract syntax:*

$$\mathbb{T} = \mathbb{C} \mid \mathbb{T} \rightarrow \mathbb{T} \mid \mathbb{T} \cap \mathbb{T}.$$

NOTATION. Upper case Roman letters i.e. A, B, \dots , will denote arbitrary types. When writing intersection types we shall use the following convention: the constructor \cap takes precedence over the constructor \rightarrow , and \rightarrow associates to the right. For example $(A \rightarrow B \rightarrow C) \cap A \rightarrow B \rightarrow C \equiv ((A \rightarrow (B \rightarrow C)) \cap A) \rightarrow (B \rightarrow C)$.

In this paper we shall be concerned with several different intersection type languages arising from taking different sets of type atoms, depending on which typing invariance properties we want to capture. Typical choices for the set of type atoms are \mathbb{C}_∞ , a countable set of constants, or finite sets like $\{\Omega, \varphi, \omega\}$ or $\{\nu\}$.

Most of the expressive power of intersection type languages comes from the fact that they are endowed with a *preorder relation*, \leq , which induces, on the set of types, the structure of a meet semi-lattice with respect to \cap . This appears natural when we think of types as sets of denotations, and interpret \cap as set-theoretic intersections and \leq as set inclusion.

Definition 2 (Intersection Type Preorder)

An intersection type preorder $\Sigma = (\mathbb{C}^\Sigma, \leq_\Sigma)$ is a binary relation \leq_Σ on $\mathbb{T}(\mathbb{C}^\Sigma)$ satisfying the set of axioms and rules of Figure 1.

NOTATION. We shall write $A \sim_\Sigma B$ when both $A \leq_\Sigma B$ and $B \leq_\Sigma A$.

Axiom (Ω) states that the type preorders containing the constant Ω have Ω itself as top element. This is particularly meaningful when used in combination with the Ω -type assignment systems, which essentially treat Ω as the universal type of all λ -terms (see Definition 14).

| | |
|--|--|
| (refl) $A \leq A$ | (idem) $A \leq A \cap A$ |
| (incl _L) $A \cap B \leq A$ | (incl _R) $A \cap B \leq B$ |

| (Ω) if $\Omega \in \mathbb{C} \quad A \leq \Omega$ | (ν) if $\nu \in \mathbb{C} \quad A \rightarrow B \leq \nu$ |

Fig. 1. Basic Axioms and Rules of Type Preorders.

Axiom (ν) states that ν is above any arrow type. This axiom agrees with the ν -type assignment systems, which treat ν as the universal type of all λ -abstractions (see Definition 16). Notice that the role of ν may be played by the type $\Omega \rightarrow \Omega$, when Ω is in \mathbb{C} . For this reason it is of no use to have at the same time ν and Ω . Hence we impose, as a pragmatic rule, that these two constants do not occur together in any \mathbb{C} .

Notice that associativity and commutativity of \cap (as always modulo \sim) follow easily from the above axioms and rules. For instance, commutativity is immediate:

$$A \cap B \leq (A \cap B) \cap (A \cap B) \leq B \cap A.$$

Since \cap is commutative and associative, we shall write $\bigcap_{i \leq n} A_i$ for $A_1 \cap \dots \cap A_n$. Similarly, we shall write $\bigcap_{i \in I} A_i$, where I denotes always a finite set. Moreover, we convene that $\bigcap_{i \in \emptyset} A_i$ is Ω when $\Omega \in \mathbb{C}$ and we forbid intersections on the empty set when $\Omega \notin \mathbb{C}$.

Remark 3 *It is not required that \sim be congruent with the constructor \rightarrow . For many type preorders this will be implied by the extra axiom (η) or (η^\sim) (see Figure 2).*

All the type preorders considered so far in the literature are defined for languages over finite or countable sets of atoms and are “generated” by recursive sets ∇ of axioms and rules of the shape $A \leq B$ (where ∇ it is said to generate \leq when $A \leq B$ holds if and only if it can be derived from the axioms and rules of ∇ together with those in Definition 2). Such generated preorders have been referred to as *type theories*. We shall denote them by $\Sigma^\nabla = (\mathbb{C}^\nabla, \leq_\nabla)$.

Note that there are only countably many possible ∇ ; hence, there are uncountably many preorders which cannot be represented this way. Note also that the correspondence $\nabla \mapsto \leq_\nabla$ is not injective.

In this paper we try to be as general as possible, sticking to our notion of type preorder which indeed extends the notion of type preorders usually considered in the literature, where rules (Ω) and (ν) are not taken into account and are instead

postulated inside the recursive sets generating the type preorder.

Figure 2 shows a list of special purpose axioms and rules which have been considered in the literature, and which we shall briefly discuss in the following.

| | | | |
|--------------------------------|--|---------------------------------|--|
| $(\Omega\text{-}\eta)$ | $\Omega \leq \Omega \rightarrow \Omega$ | $(\rightarrow\text{-}\cap)$ | $(A \rightarrow B) \cap (A \rightarrow C) \leq A \rightarrow B \cap C$ |
| $(\Omega\text{-}lazy)$ | $A \rightarrow B \leq \Omega \rightarrow \Omega$ | $(\rightarrow\text{-}\cap\sim)$ | $(A \rightarrow B) \cap (A \rightarrow C) \sim A \rightarrow B \cap C$ |
| (η) | $\frac{A' \leq A \quad B \leq B'}{A \rightarrow B \leq A' \rightarrow B'}$ | $(\eta\sim)$ | $\frac{A' \sim A \quad B \sim B'}{A \rightarrow B \sim A' \rightarrow B'}$ |
| $(\omega\text{-}Scott)$ | $\Omega \rightarrow \omega \sim \omega$ | $(\omega\text{-}Park)$ | $\omega \rightarrow \omega \sim \omega$ |
| $(\omega\varphi)$ | $\omega \leq \varphi$ | $(\varphi \rightarrow \omega)$ | $\varphi \rightarrow \omega \sim \omega$ |
| $(\omega \rightarrow \varphi)$ | $\omega \rightarrow \varphi \sim \varphi$ | (I) | $(\varphi \rightarrow \varphi) \cap (\omega \rightarrow \omega) \sim \omega$ |

Fig. 2. Possible Axioms and Rules concerning \leq .

The meaning of axioms and rules of Figure 2 can be grasped if we take types to denote subsets of a domain of discourse and we look at \rightarrow as the function space constructor in the light of Curry-Scott semantics, see [30]. Thus the type $A \rightarrow B$ denotes the set of *total* functions which map each element of A into an element of B .

Since Ω represents the maximal element, i.e. the whole universe, $\Omega \rightarrow \Omega$ is the set of functions which applied to an arbitrary element return again an arbitrary element. Thus, axiom $(\Omega\text{-}\eta)$ expresses the fact that all the objects in our domain of discourse are total functions, i.e. that Ω is equal to $\Omega \rightarrow \Omega$ [9]. If now we want to capture only those terms which truly represent functions, as we do for example in the lazy λ -calculus, we cannot assume axiom $(\Omega\text{-}\eta)$. One still may postulate the weaker property $(\Omega\text{-}lazy)$ to make all functions total [2]. It simply says that an element which is a function, because it maps A into B , maps also the whole universe into itself.

The intended interpretation of arrow types motivates axiom $(\rightarrow\text{-}\cap)$, which implies that if a function maps A into B , and the same function maps also A into C , then, actually, it maps the whole A into the intersection of B and C (i.e. into $B \cap C$), see [9].

Rule (η) is also very natural in view of the set-theoretic interpretation. It implies that the arrow constructor is contra-variant in the first argument and covariant in the second one. It is clear that if a function maps A into B , and we take a subset A' of A and a superset B' of B , then this function will map also A' into B' , see [9].

The rules $(\rightarrow\text{-}\cap\sim)$ and $(\eta\sim)$ are similar to the rules $(\rightarrow\text{-}\cap)$ and (η) . They capture properties of the graph models for the untyped λ -calculus, see [28] and [19].

The remaining axioms express peculiar properties of D_∞ -like inverse limit models, see [9], [12], [11], [24], [22], [14].

We can introduce now a list of significant intersection type preorders which have been extensively considered in the literature. All these preorders have been introduced mainly to obtain corresponding filter models of (restricted) λ -calculi, as we shall discuss in Section 5. The order is logical, rather than historical, and some references define the models, others deal with the corresponding filter models: [31], [10], [23], [24], [18], [2], [9], [29], [26], [11], [28], [19], [17].

These preorders are of the form $\Sigma^\nabla = (\mathbb{C}^\nabla, \leq_\nabla)$, with various different names ∇ , picked for mnemonic reasons. In Figure 3, for each preorder Σ^∇ we list its set \mathbb{C}^∇ of constants and its set ∇ of extra axioms and rules taken from Figure 2. Here \mathbb{C}_∞ is an infinite set of fresh atoms (i.e. different from $\Omega, \nu, \varphi, \omega$).

Fig. 3. Particular Atoms, Axioms and Rules.

We define two conditions on type preorders to be used in our characterisation results for rule β .

Definition 4 (Beta and ν -sound Preorders)

(1) A type preorder Σ is beta iff for all sets of indexes I , and all types A_i, B_i ,

C, D in $\mathbb{P}(\mathbb{C}^\Sigma)$:

$$\bigcap_{i \in I} (A_i \rightarrow B_i) \leq_\Sigma C \rightarrow D \quad \Leftrightarrow \quad \bigcap_{i \in J} B_i \leq_\Sigma D \text{ where } J = \{i \in I \mid C \leq A_i\}.$$

(2) A type preorder Σ is ν -sound iff for all $A, B \in \mathbb{P}(\mathbb{C}^\Sigma)$:

$$\nu \not\leq_\Sigma A \rightarrow B.$$

A few comments on the previous definition. In the definition of beta preorders, if J is empty and $\Omega \in \mathbb{C}^\Sigma$ we get $\Omega \sim_\Sigma D$. Instead, by assumption, J can never be empty when $\Omega \notin \mathbb{C}^\Sigma$. If we look at \cap as representing join, and arrow types as representing step functions, then the condition for a type preorder of being beta is exactly the relation which holds between sups of step functions [20].

The ν -sound condition is used both to prevent ν from being a redundant type and to avoid assigning too many types to a λ -abstraction (assigning ν amounts exactly to discriminating an abstraction and nothing more). Notice that Σ is trivially ν -sound when $\nu \notin \mathbb{C}^\Sigma$.

When $\Sigma = \Sigma^\nabla$, for some ∇ , it is usually possible to prove the above defined conditions by induction on the derivation that shows that two given types are in the preorder relation. The following notion of *strong beta* is handy when proving that some of the type preorders of Figure 3 are beta. A type preorder Σ^∇ is strong beta when its set ∇ of axioms and rules contains \mathcal{BCD} and a set ∇^- of axioms with suitable properties.

Definition 5 (Strong Beta Preorders)

A type preorder Σ^∇ is strong beta if $\nabla = \mathcal{BCD} \cup \nabla^-$ and:

- (1) ∇^- contains no rule and only axioms of one of the following two shapes:
 - $\psi \leq \psi'$,
 - $\psi \sim \bigcap_{i \in I} (\psi_i^{(1)} \rightarrow \psi_i^{(2)})$,
 where $\psi, \psi', \psi_i^{(1)}, \psi_i^{(2)} \in \mathbb{C}^\nabla$, and $\psi, \psi', \psi_i^{(2)} \not\equiv \Omega$ for all $i \in I$;
- (2) for each $\psi \in \mathbb{C}^\nabla$ such that $\psi \not\equiv \Omega$ there is exactly one axiom in ∇^- of the shape $\psi \sim \bigcap_{i \in I} (\psi_i^{(1)} \rightarrow \psi_i^{(2)})$;
- (3) let ∇^- contain $\psi \sim \bigcap_{i \in I} (\psi_i^{(1)} \rightarrow \psi_i^{(2)})$ and $\psi' \sim \bigcap_{j \in J} (\psi_j'^{(1)} \rightarrow \psi_j'^{(2)})$. Then ∇^- contains also $\psi \leq \psi'$ iff for each $j \in J$ there exists $i \in I$ such that $\psi_j'^{(1)} \leq \psi_i^{(1)}$ and $\psi_i^{(2)} \leq \psi_j'^{(2)}$ are both in ∇^- .

For example the preorders $\Sigma^{\mathcal{HL}}$, $\Sigma^{\mathcal{Sc}}$, $\Sigma^{\mathcal{Pa}}$, $\Sigma^{\mathcal{CDZ}}$, $\Sigma^{\mathcal{HR}}$, and $\Sigma^{\mathcal{DHM}}$ are strong beta.

Lemma 6 Each strong beta type preorder is beta.

PROOF. We shall denote elements of \mathbb{C}^∇ by $\psi, \xi, \varphi, \zeta$ (possibly with indexes).

By assumption, for each constant $\psi \in \mathbb{C}^\nabla$ there is exactly *one* axiom stating that ψ is equivalent to an intersection of arrow types. We denote such an intersection by $\bigcap_{l \in L(\psi)} (\xi^{(\psi)} \rightarrow \zeta^{(\psi)})$. Moreover, notice that the most general form of an intersection type is a finite intersection of arrow types and type constants. We can prove two statements by simultaneous induction on the definition of \leq , the first of which implies the beta condition:

- if $(\bigcap_{i \in I} (A_i \rightarrow B_i)) \cap (\bigcap_{h \in H} \psi_h) \leq_\nabla (\bigcap_{j \in J} (C_j \rightarrow D_j)) \cap (\bigcap_{k \in K} \varphi_k)$, then $(\bigcap_{i \in I'} B_i) \cap (\bigcap_{h \in H'} (\bigcap_{l \in L(\psi_h)'} \zeta_l^{(\psi_h)})) \leq_\nabla D_j$ where $I' = \{i \in I \mid C_j \leq_\nabla A_i\}$, $H' = \{h \in H \mid C_j \leq_\nabla \xi_l^{(\psi_h)} \text{ for some } l \in L(\psi_h)\}$, $L(\psi_h)' = \{l \in L(\psi_h) \mid C_j \leq_\nabla \xi_l^{(\psi_h)}\}$;
- if $(\bigcap_{i \in I} (A_i \rightarrow B_i)) \cap (\bigcap_{h \in H} \psi_h) \leq_\nabla (\bigcap_{j \in J} (C_j \rightarrow D_j)) \cap (\bigcap_{k \in K} \varphi_k)$, then $(\bigcap_{i \in I'} B_i) \cap (\bigcap_{h \in H'} (\bigcap_{l \in L(\psi_h)'} \zeta_l^{(\psi_h)})) \leq_\nabla \zeta_m^{(\varphi_k)}$ where $I' = \{i \in I \mid \xi_m^{(\varphi_k)} \leq_\nabla A_i\}$, $H' = \{h \in H \mid \xi_m^{(\varphi_k)} \leq_\nabla \xi_l^{(\psi_h)} \text{ for some } l \in L(\psi_h)\}$, $L(\psi_h)' = \{l \in L(\psi_h) \mid \xi_m^{(\varphi_k)} \leq_\nabla \xi_l^{(\psi_h)}\}$.

Proposition 7

- (1) Type preorders of Figure 3 are beta.
- (2) Type preorders of Figure 3 are ν -sound.

PROOF. (1) For $\nabla \in \{\mathcal{B}a, \mathcal{C}D\nu, \mathcal{E}\mathcal{H}\mathcal{R}, \mathcal{A}O, \mathcal{B}\mathcal{C}\mathcal{D}, \mathcal{P}l, \mathcal{E}n\}$ we can prove, by induction on the definition of \leq_∇ , that

$$\left(\bigcap_{i \in I} (A_i \rightarrow B_i) \right) \cap \left(\bigcap_{h \in H} \psi_h \right) \leq_\nabla \left(\bigcap_{j \in J} (C_j \rightarrow D_j) \right) \cap \left(\bigcap_{k \in K} \xi_k \right) \Rightarrow \bigcap_{i \in I'} B_i \leq_\nabla D_j,$$

where $I' = \{i \in I \mid C_j \leq_\nabla A_i\}$.

The preorders Σ^∇ for $\nabla \in \{\mathcal{H}\mathcal{L}, \mathcal{S}c, \mathcal{P}a, \mathcal{C}\mathcal{D}\mathcal{Z}, \mathcal{H}\mathcal{R}, \mathcal{D}\mathcal{H}\mathcal{M}\}$ are beta by Lemma 6.

(2) For $\Sigma^{\mathcal{E}\mathcal{H}\mathcal{R}}$ one can easily show, by induction on $\leq_{\mathcal{E}\mathcal{H}\mathcal{R}}$, that $\nu \leq_{\mathcal{E}\mathcal{H}\mathcal{R}} A$ implies that A is an intersection of ν .

Example 8 An example of a non-beta preorder is Σ^\diamond , defined by $\mathbb{C}^\diamond = \{\Omega, \diamond, \heartsuit\}$ and $\diamond = \mathcal{B}\mathcal{C}\mathcal{D} \cup \{(\diamond)\}$, where

$$(\diamond) A \leq A[\diamond := \heartsuit].$$

Σ^\diamond is not beta, since $\diamond \rightarrow \diamond \leq_\diamond \heartsuit \rightarrow \heartsuit$, but $\heartsuit \not\leq_\diamond \diamond$.

NOTATION. We write “the type preorder Σ validates ∇ ” to mean that all axioms and rules of ∇ are admissible in Σ .

In order to characterise the invariance of typing under η -expansion, we need to introduce a further condition on type preorders, which essentially says that each atomic type either is greater than or equal to a type which can be deduced for all terms which are abstractions (see Definition 16), or it is between two intersections of “strictly related” arrow types, as specified in the following definition.

Definition 9 (Eta Preorders) *A type preorder Σ is eta iff for all $\psi \in \mathbb{C}^\Sigma$ one of these two conditions hold:*

- $\nu \leq_\Sigma \psi$
- *there exist non-empty families of types $\{A_i, B_i\}_{i \in I}$, $\{D_{i,j}, E_{i,j}\}_{j \in J_i}$ in $\mathbb{P}(\mathbb{C}^\Sigma)$ such that*

$$\begin{aligned} \bigcap_{i \in I} (A_i \rightarrow B_i) \leq_\Sigma \psi \leq_\Sigma \bigcap_{i \in I'} (\bigcap_{j \in J_i} (D_{i,j} \rightarrow E_{i,j})) \quad \& \\ \forall i \in I'. A_i \leq_\Sigma \bigcap_{j \in J_i} D_{i,j} \quad \& \quad \bigcap_{j \in J_i} E_{i,j} \leq_\Sigma B_i, \end{aligned}$$

where $I' = \{i \in I \mid B_i \not\leq_\Sigma \Omega\}$.

It is easy to verify that if either $\Omega \notin \mathbb{C}^\Sigma$ and Σ validates \mathcal{CDV} or $\Omega \in \mathbb{C}^\Sigma$ and Σ validates \mathcal{AO} , then the condition of the above definition simplifies to the requirement that all atomic types are either greater than ν or greater than $\Omega \rightarrow \Omega$, or they are equivalent to a suitable intersection of arrow types, namely

$$\forall \psi \in \mathbb{C}^\Sigma. \nu \leq_\Sigma \psi \text{ or } \Omega \rightarrow \Omega \leq_\Sigma \psi \text{ or } \exists I, \{A_i, B_i\}_{i \in I}. \bigcap_{i \in I} (A_i \rightarrow B_i) \sim_\Sigma \psi.$$

The following proposition singles out all type preorders of Figure 3 which are eta: the proof is trivial.

Proposition 10 *If $\nabla \in \{\mathcal{HL}, \mathcal{EHR}, \mathcal{AO}, \mathcal{Sc}, \mathcal{Pa}, \mathcal{CDZ}, \mathcal{DHM}\}$, then Σ^∇ is a eta preorder.*

3 Intersection Type Assignments

We are now ready to introduce the crucial notion of *intersection type assignment system*. First we need a few preliminary definitions.

Definition 11 (1) *A Σ -basis is a set of statements of the shape $x:B$, where $B \in \mathbb{P}(\mathbb{C}^\Sigma)$. All term variables occurring in a Σ -basis are distinct.*

- (2) *An intersection-type assignment system relative to Σ , denoted by $\lambda \cap^\Sigma$, is a formal system for deriving judgements of the form $\Gamma \vdash^\Sigma M : A$, where the subject M is a λ -term, the predicate A is in $\mathbb{P}(\mathbb{C}^\Sigma)$, and Γ is a Σ -basis.*

We shall consider λ -terms up to α -conversion and we shall assume the Barendregt convention on variables [8] to be fulfilled. The Barendregt convention for judg-

$$\begin{array}{c}
(\text{Ax}) \quad \Gamma, x:A \vdash_{\mathcal{B}}^{\Sigma} x:A \\
(\rightarrow \text{I}) \quad \frac{\Gamma, x:A \vdash_{\mathcal{B}}^{\Sigma} M : B}{\Gamma \vdash_{\mathcal{B}}^{\Sigma} \lambda x.M : A \rightarrow B} \quad (\rightarrow \text{E}) \quad \frac{\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : A \rightarrow B \quad \Gamma \vdash_{\mathcal{B}}^{\Sigma} N : A}{\Gamma \vdash_{\mathcal{B}}^{\Sigma} MN : B} \\
(\cap \text{I}) \quad \frac{\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : A \quad \Gamma \vdash_{\mathcal{B}}^{\Sigma} M : B}{\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : A \cap B} \quad (\leq) \quad \frac{\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : A \quad A \leq_{\Sigma} B}{\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : B}
\end{array}$$

Fig. 4. The Axioms and Rules of the Basic Type Assignment System.

ments $\Gamma \vdash^{\Sigma} M : A$ implies that variables occurring in the Σ -basis Γ cannot occur bound in the term M .

NOTATION. If Γ is a Σ -basis then $x \in \Gamma$ is short for $(x : A) \in \Gamma$ for some A .

If Γ is a Σ -basis and $A \in \mathbb{T}(\mathbb{C}^{\Sigma})$ then $\Gamma, x : A$ is short for $\Gamma \cup \{x : A\}$ when $x \notin \Gamma$.

When $\Sigma = \Sigma^{\nabla}$ we shall denote $\lambda \cap^{\Sigma}$ and \vdash^{Σ} by $\lambda \cap^{\nabla}$ and \vdash^{∇} , respectively.

Various type assignment systems can be defined, each of them parametrized with a particular type preorder Σ . The simplest system is given in the following definition.

Definition 12 (Basic Type Assignment System)

Given a type preorder Σ , the axioms and rules of the basic type assignment system, denoted by $\lambda \cap_{\mathcal{B}}^{\Sigma}$, for deriving judgements $\Gamma \vdash_{\mathcal{B}}^{\Sigma} M : A$, are shown in Figure 4.

Example 13 Self-application can be easily typed in $\lambda \cap_{\mathcal{B}}^{\Sigma}$, as follows.

$$\frac{\frac{\frac{x:(A \rightarrow B) \cap A \vdash_{\mathcal{B}}^{\Sigma} x:(A \rightarrow B) \cap A}{x:(A \rightarrow B) \cap A \vdash_{\mathcal{B}}^{\Sigma} x:A \rightarrow B} (\leq) \quad \frac{x:(A \rightarrow B) \cap A \vdash_{\mathcal{B}}^{\Sigma} x:(A \rightarrow B) \cap A}{x:(A \rightarrow B) \cap A \vdash_{\mathcal{B}}^{\Sigma} x:A} (\leq)}{\frac{x:(A \rightarrow B) \cap A \vdash_{\mathcal{B}}^{\Sigma} xx:B}{\vdash_{\mathcal{B}}^{\Sigma} \lambda x.xx : (A \rightarrow B) \cap A \rightarrow B} (\rightarrow \text{E})} (\rightarrow \text{I})$$

If $\Omega \in \mathbb{C}$, a natural choice is to set Ω as the universal type of all λ -terms. This amounts modifying the basic type assignment system by adding a suitable axiom for Ω .

Definition 14 (Ω -type Assignment System)

Given a type preorder Σ with $\Omega \in \mathbb{C}^{\Sigma}$, the axioms and rules of the Ω -type assignment system (denoted $\lambda \cap_{\Omega}^{\Sigma}$), for deriving judgements of the form $\Gamma \vdash_{\Omega}^{\Sigma} M : A$, are those

of the basic one, plus the axiom

$$(Ax-\Omega) \quad \Gamma \vdash_{\Omega}^{\Sigma} M : \Omega.$$

Example 15 Also non-strongly normalising terms can be typed in $\lambda\cap_{\Omega}^{\Sigma}$ even with a type different from Ω . Note the usage of the axiom $(Ax-\Omega)$. Let $\Delta \equiv \lambda x.x x$.

$$\frac{\frac{x:A, y:\Omega \vdash_{\Omega}^{\Sigma} x : A}{y:\Omega \vdash_{\Omega}^{\Sigma} \lambda x.x : A \rightarrow A} (\rightarrow I)}{\vdash_{\Omega}^{\Sigma} \lambda y x.x : \Omega \rightarrow A \rightarrow A} (\rightarrow I) \quad \vdash_{\Omega}^{\Sigma} \Delta\Delta : \Omega \quad (\rightarrow E)}{\vdash_{\Omega}^{\Sigma} (\lambda y x.x)(\Delta\Delta) : A \rightarrow A} (\rightarrow E)$$

Analogously to the case of Ω , when $\nu \in \mathbb{C}$, it is natural to consider ν as the universal type for abstractions, hence modifying the basic system by adding a special axiom for ν .

Definition 16 (ν -type Assignment System)

Given a type preorder Σ with $\nu \in \mathbb{C}^{\Sigma}$, the axioms and rules of the ν -type assignment system (denoted $\lambda\cap_{\nu}^{\Sigma}$), for deriving judgements of the form $\Gamma \vdash_{\nu}^{\Sigma} M : A$, are those of the basic one, plus the axiom

$$(Ax-\nu) \quad \Gamma \vdash_{\nu}^{\Sigma} \lambda x.M : \nu.$$

Example 17 Axiom $(Ax-\nu)$ allows again to type non-strongly normalising terms. Notice that the term of Example 15 is not typable in $\lambda\cap_{\nu}^{\Sigma} \mathcal{HR}$, as proved in [18].

$$\frac{\frac{x:A, y:\nu \vdash_{\nu}^{\Sigma} x : A}{y:\nu \vdash_{\nu}^{\Sigma} \lambda x.x : A \rightarrow A} (\rightarrow I)}{\vdash_{\nu}^{\Sigma} \lambda y x.x : \nu \rightarrow A \rightarrow A} (\rightarrow I) \quad \vdash_{\nu}^{\Sigma} \lambda z.\Delta\Delta : \nu \quad (\rightarrow E)}{\vdash_{\nu}^{\Sigma} (\lambda y x.x)(\lambda z.\Delta\Delta) : A \rightarrow A} (\rightarrow E)$$

For simplicity we assume the symbols Ω and ν to be reserved for the universal type constants respectively used in the systems $\lambda\cap_{\Omega}^{\Sigma}$ and $\lambda\cap_{\nu}^{\Sigma}$, i.e. we forbid $\Omega \in \mathbb{C}^{\Sigma}$ or $\nu \in \mathbb{C}^{\Sigma}$ when we deal with $\lambda\cap_{\mathcal{B}}^{\Sigma}$.

NOTATION. In the following, $\lambda\cap^{\Sigma}$ will range over $\lambda\cap_{\mathcal{B}}^{\Sigma}$, $\lambda\cap_{\Omega}^{\Sigma}$ and $\lambda\cap_{\nu}^{\Sigma}$. More precisely, we shall assume that $\lambda\cap^{\Sigma}$ stands for $\lambda\cap_{\Omega}^{\Sigma}$ whenever $\Omega \in \mathbb{C}^{\Sigma}$, for $\lambda\cap_{\nu}^{\Sigma}$ whenever $\nu \in \mathbb{C}^{\Sigma}$, and for $\lambda\cap_{\mathcal{B}}^{\Sigma}$ otherwise. Similarly, for \vdash^{Σ} . If there is no danger of confusion, we write simply \vdash for \vdash^{Σ} .

The subterm property does not hold in general for $\lambda\cap_{\nu}^{\Sigma}$. In fact, $\lambda x.M$ is typable also when M is not typable. Moreover, in $\lambda\cap_{\Omega}^{\Sigma}$ and $\lambda\cap_{\nu}^{\Sigma}$, a judgement $\Gamma \vdash^{\Sigma} M : A$ does not imply $FV(M) \subseteq \Gamma$.

One of the most interesting features of intersection type systems is that of enabling precise characterisation results of many important sets of λ -terms, among which the one of Strongly-Normalizing terms. Such a result is stated in the following theorem and it will be used in the next section (for a proof see [17].³)

Theorem 18 (*Characterisation of Strongly Normalising Terms*) *A λ -term M is strongly normalising iff for all type preorders Σ , there exist $A \in \mathbb{T}(\mathbb{C}^\Sigma)$ and a Σ -basis Γ such that $\Gamma \vdash_{\mathbb{B}}^\Sigma M : A$.*

We end this subsection by defining the union between Σ -basis which requires some care in the presence of the intersection type constructor.

Definition 19 $\Gamma_1 \uplus \Gamma_2 = \{(x:A) \mid (x:A) \in \Gamma_1 \text{ and } x \notin \Gamma_2\} \cup$
 $\{(x:A) \mid (x:A) \in \Gamma_2 \text{ and } x \notin \Gamma_1\} \cup$
 $\{(x:A_1 \cap A_2) \mid (x:A_1) \in \Gamma_1 \text{ and } (x:A_2) \in \Gamma_2\}$

In the rest of this section we shall introduce a few relevant properties of intersection types, needed for our characterisation results in the following section.

3.1 Admissible Rules

Many interesting type assignment rules can be proved to be admissible.

Proposition 20 (Admissible Rules) *For any type preorder Σ , the following rules are admissible in the intersection type assignment system $\lambda \cap^\Sigma$.*

$$\begin{array}{ll}
(\cap E_l) \frac{\Gamma \vdash^\Sigma M : A \cap B}{\Gamma \vdash^\Sigma M : A} & (\cap E_r) \frac{\Gamma \vdash^\Sigma M : A \cap B}{\Gamma \vdash^\Sigma M : B} \\
(W) \frac{\Gamma \vdash^\Sigma M : A \quad x \notin \Gamma}{\Gamma, x:B \vdash^\Sigma M : A} & (S) \frac{\Gamma, x:B \vdash^\Sigma M : A \quad x \notin FV(M)}{\Gamma \vdash^\Sigma M : A} \\
(C) \frac{\Gamma, x:B \vdash^\Sigma M : A \quad \Gamma \vdash^\Sigma N : B}{\Gamma \vdash^\Sigma M[x := N] : A} & (\leq L) \frac{\Gamma, x:B \vdash^\Sigma M : A \quad C \leq_\Sigma B}{\Gamma, x:C \vdash^\Sigma M : A}
\end{array}$$

In the following we shall freely use the rules of the above Proposition.

³ The type systems considered in [17] are induced by type theories instead of type preorders, but the arguments given there to show the characterisation of strongly normalising terms extend without changes to type preorders.

3.2 Generation Lemmata

We introduce now a few properties enabling to “reverse” some of the rules of the type assignment systems $\lambda\cap^\Sigma$, so as to achieve some form of generation (or inversion) lemmas (see Theorems 21 and 22).

Such properties are not trivial. For instance, for the arrow elimination rule, in general we can only say that when $\Gamma \vdash^\Sigma MN : A$, then there are a non-empty, finite set I and types B_i, C_i , such that for each $i \in I$, $\Gamma \vdash^\Sigma M : B_i \rightarrow C_i$, $\Gamma \vdash^\Sigma N : B_i$, and moreover $\bigcap_{i \in I} C_i \leq_\Sigma A$. Reasoning similarly on the rule $(\rightarrow I)$, one can conclude again that it cannot be reversed. More formally, we get the following theorem.

NOTATION. When we write “...assume $A \not\prec_\Sigma \Omega$...” we mean that this condition is always true when we deal with \vdash_B^Σ and \vdash_ν^Σ , while it must be checked for \vdash_Ω^Σ . Similarly, the condition $\nu \not\prec_\Sigma A$ must be checked just for \vdash_ν^Σ .

Theorem 21 (Generation Lemma I) *Let Σ be a type preorder.*

- (1) *Assume $A \not\prec_\Sigma \Omega$. Then $\Gamma \vdash^\Sigma MN : A$ iff $\Gamma \vdash^\Sigma M : B_i \rightarrow C_i$, $\Gamma \vdash^\Sigma N : B_i$, and $\bigcap_{i \in I} C_i \leq_\Sigma A$ for some non-empty set I and types $B_i, C_i \in \mathbb{P}(\mathbb{C}^\Sigma)$.*
- (2) *Assume $\nu \not\prec_\Sigma A$. Then $\Gamma \vdash^\Sigma \lambda x.M : A$ iff $\Gamma, x:B_i \vdash^\Sigma M : C_i$, and $\bigcap_{i \in I} (B_i \rightarrow C_i) \leq_\Sigma A$ for some non-empty set I and types $B_i, C_i \in \mathbb{P}(\mathbb{C}^\Sigma)$.*

PROOF. The proof of each (\Leftarrow) is easy. So we only treat (\Rightarrow) .

(1) By induction, on derivations. The only interesting case is when $A \equiv A_1 \cap A_2$ and the last applied rule is $(\cap I)$:

$$(\cap I) \frac{\Gamma \vdash^\Sigma MN : A_1 \quad \Gamma \vdash^\Sigma MN : A_2}{\Gamma \vdash^\Sigma MN : A_1 \cap A_2}.$$

The condition $A \not\prec_\Sigma \Omega$ implies that we cannot have $A_1 \sim_\Sigma A_2 \sim_\Sigma \Omega$. We do the proof for $A_1 \not\prec_\Sigma \Omega$ and $A_2 \not\prec_\Sigma \Omega$, the other cases can be treated similarly. By induction, there are I, B_i, C_i, J, D_j, E_j such that

$$\begin{aligned} \forall i \in I. \quad & \Gamma \vdash^\Sigma M : B_i \rightarrow C_i, \Gamma \vdash^\Sigma N : B_i, \\ \forall j \in J. \quad & \Gamma \vdash^\Sigma M : D_j \rightarrow E_j, \Gamma \vdash^\Sigma N : D_j, \\ \bigcap_{i \in I} C_i \leq_\Sigma A_1 \quad & \& \quad \bigcap_{j \in J} E_j \leq_\Sigma A_2. \end{aligned}$$

So we are done since $(\bigcap_{i \in I} C_i) \cap (\bigcap_{j \in J} E_j) \leq_\Sigma A$.

(2) The proof is very similar to the proof of (1). It is again by induction on deriva-

tions and again the only interesting case is when the last applied rule is (\cap I):

$$(\cap\text{I}) \frac{\Gamma \vdash^\Sigma \lambda x.M : A_1 \quad \Gamma \vdash^\Sigma \lambda x.M : A_2}{\Gamma \vdash^\Sigma \lambda x.M : A_1 \cap A_2}.$$

The condition $\nu \not\leq_\Sigma A$ implies that we cannot have $\nu \leq_\Sigma A_1$ and $\nu \leq_\Sigma A_2$. We do the proof for $\nu \not\leq_\Sigma A_1$ and $\nu \not\leq_\Sigma A_2$. By induction, there are I, B_i, C_i, J, D_j, E_j such that

$$\begin{aligned} \forall i \in I. \Gamma, x : B_i \vdash^\Sigma M : C_i, \forall j \in J. \Gamma, x : D_j \vdash^\Sigma M : E_j, \\ \bigcap_{i \in I} (B_i \rightarrow C_i) \leq_\Sigma A_1 \quad \& \quad \bigcap_{j \in J} (D_j \rightarrow E_j) \leq_\Sigma A_2. \end{aligned}$$

So we are done, since $(\bigcap_{i \in I} (B_i \rightarrow C_i)) \cap (\bigcap_{j \in J} (D_j \rightarrow E_j)) \leq_\Sigma A$. The other two cases are easier. For instance, if $\nu \not\leq_\Sigma A_1$ and $\nu \sim_\Sigma A_2$, it is sufficient to take $\bigcap_{i \in I} (B_i \rightarrow C_i)$ above to conclude.

Using the properties introduced in Definition 4, we can give now a rather powerful generation lemma for $\lambda \cap^\Sigma$, which is one of the essential ingredients for the proofs of our results. We use the notion of ‘‘validation’’ introduced at page 9.

Special cases of this theorem have been previously proved in [9], [12], [11], [24], and [18].

Theorem 22 (Generation Lemma II) *Let Σ be a type preorder.*

- (1) *Assume $A \not\leq_\Sigma \Omega$. Then $\Gamma \vdash^\Sigma x : A$ iff $(x : B) \in \Gamma$ and $B \leq_\Sigma A$ for some $B \in \mathbb{P}(\mathbb{C}^\Sigma)$.*
- (2) *Assume $A \not\leq_\Sigma \Omega$ and let Σ validate $\mathcal{C}\mathcal{D}\mathcal{V}$. Then $\Gamma \vdash^\Sigma MN : A$ iff $\Gamma \vdash^\Sigma M : B \rightarrow A$, and $\Gamma \vdash^\Sigma N : B$ for some $B \in \mathbb{P}(\mathbb{C}^\Sigma)$.*
- (3) *Let Σ be ν -sound and beta. Then $\Gamma \vdash^\Sigma \lambda x.M : B \rightarrow C$ iff $\Gamma, x : B \vdash^\Sigma M : C$.*

PROOF. The proof of each (\Leftarrow) is easy. So we only treat (\Rightarrow).

(1) Easy by induction on derivations, since only the axioms (Ax), (Ax- Ω), and the rules (\cap I), (\leq) can be applied. Notice that the condition $A \not\leq_\Sigma \Omega$ implies that $\Gamma \vdash^\Sigma x : A$ cannot be obtained just using axioms (Ax- Ω).

(2) Let I, B_i, C_i be as in Theorem 21(1). Applying rule (\cap I) to $\Gamma \vdash^\Sigma M : B_i \rightarrow C_i$ we can derive $\Gamma \vdash^\Sigma M : \bigcap_{i \in I} (B_i \rightarrow C_i)$, so by rule (\leq) we have $\Gamma \vdash^\Sigma M : \bigcap_{i \in I} B_i \rightarrow \bigcap_{i \in I} C_i$. In fact, by rule (η) and axiom (\rightarrow - \cap) we get $\bigcap_{i \in I} (B_i \rightarrow C_i) \leq_\Sigma \bigcap_{i \in I} (\bigcap_{i \in I} B_i \rightarrow C_i) \leq_\Sigma \bigcap_{i \in I} B_i \rightarrow \bigcap_{i \in I} C_i$. We can choose $B = \bigcap_{i \in I} B_i$ and conclude $\Gamma \vdash^\Sigma M : B \rightarrow A$, since $\bigcap_{i \in I} C_i \leq_\Sigma A$.

(3) By the ν -soundness of Σ , we cannot have $\nu \sim_\Sigma B \rightarrow C$. Let I, B_i, C_i be as in Theorem 21(2), where $A \equiv B \rightarrow C$. Then $\bigcap_{i \in I} (B_i \rightarrow C_i) \leq_\Sigma B \rightarrow C$ implies that

$\bigcap_{i \in J} C_i \leq_{\Sigma} C$ where $J = \{i \in I \mid B \leq_{\Sigma} B_i\}$, since Σ is beta. From $\Gamma, x:B_i \vdash^{\Sigma} M : C_i$ we can derive $\Gamma, x:B \vdash^{\Sigma} M : C_i$ using rule (\leq L), so by (\cap I) we have $\Gamma, x:B \vdash^{\Sigma} M : \bigcap_{i \in J} C_i$. Finally, applying rule (\leq), we can conclude $\Gamma, x:B \vdash^{\Sigma} M : C$.

4 Characterisation of Subject Reduction and Expansion

In the literature, to which we have provided many references in the previous sections, many models for the λ -calculus and a number of its restrictions have been shown to be finitary representable by means of (intersection) types. We now address, from the “intersection type point of view”, the generic requirements (a) and (b) concerning soundness discussed in the introduction. In particular, we shall characterise those intersection type systems in which types are preserved under various notions of conversions: β , η , together with some of their *restrictions* inspired by λ -calculi considered in the literature.

Let us first give the definitions of these restricted redexes.

Definition 23 (Restricted Redexes)

- (1) A redex $(\lambda x.M)N$ is a **var** β -redex if N is a variable.
- (2) A redex $(\lambda x.M)N$ is a **fun** β -redex if N is an abstraction.
- (3) A redex $(\lambda x.M)N$ is an **id** β -redex if $x \in FV(M)$.
- (4) A redex $(\lambda x.M)N$ is a **norm** β -redex if N is a closed strongly normalising term.

The “call-by-value” λ -calculus is obtained by restricting to **var** β - and **fun** β -redexes (usually called β_v -redexes) [27], the $\lambda\mathbf{I}$ -calculus by allowing to abstract only variables which occur free in the bodies (in this way we only get a proper subset of the set of **id** β -redexes, whose elements are usually called **$\beta\mathbf{I}$** -redexes) [13] and the $\lambda\mathbf{KN}$ -calculus by restricting to **var** β -, **id** β - and **norm** β -redexes [23].

We shall deal now with rules of the form

$$(\mathbf{R-exp}) \quad \frac{M \rightarrow_{\mathbf{R}} N \quad \Gamma \vdash N : A}{\Gamma \vdash M : A} \quad (\mathbf{R-red}) \quad \frac{M \rightarrow_{\mathbf{R}} N \quad \Gamma \vdash M : A}{\Gamma \vdash N : A}$$

where $\rightarrow_{\mathbf{R}}$ denotes the reduction relation obtained by restricting the contraction to the set of **R**-redexes. Admissibility of the above rules in a type assignment is usually referred to as *subject expansion* and *subject reduction*, respectively.

Theorem 24 (Characterisation of Subject R-conversion)

- (1) If $\Gamma \vdash^{\Sigma} M[x := N] : A$ and $\Gamma \vdash^{\Sigma} N : B$, then $\Gamma, x : B' \vdash^{\Sigma} M : A$ and $\Gamma \vdash^{\Sigma} N : B'$ for some $B' \in \Pi(\mathbb{C}^{\Sigma})$.

(2) (**R-expansion**) Rule (**R-exp**) is admissible in $\lambda\cap^\Sigma$ iff for all **R-redexes** $(\lambda x.M)N$ and for all contexts Γ :

N is typable in Γ whenever $M[x := N]$ is typable in Γ .

(3) (**R-reduction**) Rule (**R-red**) is admissible in $\lambda\cap^\Sigma$ iff rule $(\rightarrow \mathbf{I})$ can be reversed for **R-redexes**, i.e. for all Γ, M, A, B such that $(\lambda x.M)N$ is a **R-redex** for some N :

$$\Gamma \vdash^\Sigma \lambda x.M : B \rightarrow A \Rightarrow \Gamma, x:B \vdash^\Sigma M : A.$$

PROOF. (1) If $A \sim_\Sigma \Omega$ we can choose $B' = \Omega$. Otherwise the proof is by structural induction on M .

If $M \equiv y \neq x$ we can choose $B' = B$.

If $M \equiv x$, then $M[x := N] \equiv N$ and we can choose $B' = A$.

If $M \equiv M_1 M_2$ then, by Theorem 21(1), there are I, C_i, D_i such that $\Gamma \vdash^\Sigma M_1[x := N] : C_i \rightarrow D_i$, $\Gamma \vdash^\Sigma M_2[x := N] : C_i$, for all $i \in I$, and $\bigcap_{i \in I} D_i \leq_\Sigma A$. By induction, there are $B_i^{(1)}, B_i^{(2)}$ such that $\Gamma, x : B_i^{(1)} \vdash^\Sigma M_1 : C_i \rightarrow D_i$, $\Gamma \vdash^\Sigma N : B_i^{(1)}$, $\Gamma, x : B_i^{(2)} \vdash^\Sigma M_2 : C_i$ and $\Gamma \vdash^\Sigma N : B_i^{(2)}$ for $i \in I$. Then we can choose $B' = \bigcap_{i \in I} (B_i^{(1)} \cap B_i^{(2)})$. By rule $(\leq \mathbf{L})$, we get $\Gamma, x : B' \vdash^\Sigma M_1 : C_i \rightarrow D_i$, $\Gamma, x : B' \vdash^\Sigma M_2 : C_i$ and, by rule $(\cap \mathbf{I})$, $\Gamma \vdash^\Sigma N : B'$. So we conclude using rules $(\rightarrow \mathbf{E})$, $(\cap \mathbf{I})$, and (\leq) .

If $M \equiv \lambda x.M'$ and $\nu \leq_\Sigma A$ then we can choose $B' = B$ since by rule (ν) $\Gamma, x : B \vdash^\Sigma \lambda x.M' : \nu$ and we conclude using rule (\leq) . Otherwise, by Theorem 21(2), there are I, C_i, D_i such that $\Gamma, y : C_i \vdash^\Sigma M'[x := N] : D_i$, for all $i \in I$ and $\bigcap_{i \in I} (C_i \rightarrow D_i) \leq_\Sigma A$. By induction, there are B_i such that $\Gamma, y : C_i, x : B_i \vdash^\Sigma M' : D_i$ and $\Gamma \vdash^\Sigma N : B_i$, for $i \in I$. Choosing $B' = \bigcap_{i \in I} B_i$, we get, by rule $(\leq \mathbf{L})$, $\Gamma, y : C_i, x : B' \vdash^\Sigma M' : D_i$, and, by rule $(\cap \mathbf{I})$, $\Gamma \vdash^\Sigma N : B'$. We conclude using rules $(\rightarrow \mathbf{I})$, $(\cap \mathbf{I})$ and (\leq) .

(2) (\Rightarrow) Clearly, if N is not typable in the context Γ then also $(\lambda x.M)N$ has no type in Γ by Theorem 21(1).

(\Leftarrow) It suffices to show that $\Gamma \vdash^\Sigma M[x := N] : A$ implies $\Gamma \vdash^\Sigma (\lambda x.M)N : A$ whenever $(\lambda x.M)N$ is an **R-redex**. By hypothesis, $\Gamma \vdash^\Sigma N : B$ for some B and then, by point (1) $\Gamma, x : B' \vdash^\Sigma M : A$ and $\Gamma \vdash^\Sigma N : B'$ for some B' . We conclude using rules $(\rightarrow \mathbf{I})$ and $(\rightarrow \mathbf{E})$.

(3) (\Rightarrow) Assume $\Gamma \vdash^\Sigma \lambda x.M : B \rightarrow A$, which implies $\Gamma, y:B \vdash^\Sigma (\lambda x.M)y : A$ by rules (\mathbf{W}) and $(\rightarrow \mathbf{E})$, for a fresh y . The admissibility of rule (**R-red**) gives us $\Gamma, y:B \vdash^\Sigma M[x := y] : A$. Hence $\Gamma, x:B \vdash^\Sigma M : A$.

(\Leftarrow) It suffices to show that $\Gamma \vdash^\Sigma (\lambda x.M)N : A$ implies $\Gamma \vdash^\Sigma M[x := N] : A$ whenever $(\lambda x.M)N$ is an \mathbf{R} -redex. The case $A \sim_\Sigma \Omega$ is trivial for $\lambda\cap_\Omega^\Sigma$. Otherwise, by Theorem 21(1), there exists a finite set I and types B_i, C_i such that $\Gamma \vdash^\Sigma \lambda x.M : B_i \rightarrow C_i$, $\Gamma \vdash^\Sigma N : B_i$ and $\bigcap_{i \in I} C_i \leq_\Sigma A$. By hypothesis, we get $\Gamma, x:B_i \vdash^\Sigma M : C_i$. Then $\Gamma \vdash^\Sigma M[x := N] : C_i$ follows by an application of rule (C), and so we can conclude $\Gamma \vdash^\Sigma M[x := N] : A$ using rules (\cap I) and (\leq).

By Theorems 22(3) and 24(3) we immediately get a condition which assures Subject β -reduction.

Corollary 25 *If Σ is ν -sound and beta then rule (β -red) is admissible in $\lambda\cap^\Sigma$.*

The condition of Theorem 24(2) above is immediately met in $\lambda\cap_\Omega^\Sigma$, in $\lambda\cap_B^\Sigma$ when $x \in FV(M)$ and in $\lambda\cap_\nu^\Sigma$ when N is an abstraction. We can discuss the admissibility and non-admissibility of restricted β -expansions for our type systems.

Corollary 26

- (1) *Rule ($\mathbf{var}\beta$ -exp) is admissible in all $\lambda\cap_\Omega^\Sigma$, but never in $\lambda\cap_B^\Sigma$ and $\lambda\cap_\nu^\Sigma$.*
- (2) *Rule ($\mathbf{fun}\beta$ -exp) is admissible in all $\lambda\cap_\Omega^\Sigma$ and $\lambda\cap_\nu^\Sigma$, but never in $\lambda\cap_B^\Sigma$.*
- (3) *Rule ($\mathbf{id}\beta$ -exp) is admissible in all $\lambda\cap_B^\Sigma$ and $\lambda\cap_\Omega^\Sigma$, but never in $\lambda\cap_\nu^\Sigma$.*
- (4) *Rule ($\mathbf{norm}\beta$ -exp) is admissible in all $\lambda\cap^\Sigma$.*
- (5) *Rule (β -exp) is admissible in all $\lambda\cap_\Omega^\Sigma$, but never in $\lambda\cap_B^\Sigma$ and $\lambda\cap_\nu^\Sigma$.*

PROOF. Each of the five admissibilities but (4) follows from Theorem 24(2).

Item (4) is a consequence of Theorem 18, stating that each strongly normalising term is typable in all intersection type systems from a suitable basis. So all closed strongly normalising terms are typable in all intersection type systems starting from the empty basis.

For the non-admissibility of rules ($\mathbf{var}\beta$ -exp) and (β -exp) in $\lambda\cap_B^\Sigma$ and in $\lambda\cap_\nu^\Sigma$, notice that we can always derive $\vdash^\Sigma \lambda x.x : A \rightarrow A$, but by the Generation Lemmas I and II (Theorems 21(1) and 22(1)) we cannot derive the same type for $(\lambda yx.x)z$ from the empty basis without using (Ax- Ω).

An example showing that ($\mathbf{fun}\beta$ -exp) is not admissible in $\lambda\cap_B^\Sigma$ is $\vdash_B^\Sigma \lambda x.x : A \rightarrow A$ and $\not\vdash_B^\Sigma (\lambda yx.x)(\lambda t.z) : A \rightarrow A$.

An example showing that ($\mathbf{id}\beta$ -exp) is not admissible in $\lambda\cap_\nu^\Sigma$ is $\vdash_\nu^\Sigma \lambda x.z : \nu$ and $\not\vdash_\nu^\Sigma (\lambda yx.y)z : \nu$. Rule ($\mathbf{id}\beta$ -exp) is not admissible also for terms of the $\lambda\mathbf{I}$ -calculus since $\vdash_\nu^\Sigma \lambda x.zx : \nu$ and $\not\vdash_\nu^\Sigma (\lambda yx.yx)z : \nu$.

Notice that there are β -redexes that, without being $\mathbf{norm}\beta$ -redexes, are typable

whenever their contracta are. As an example take $(\lambda x.y)y$.

We end this section with the characterisation of Subject Reduction and Expansion for the η -rule.

Theorem 27 (Characterisation of Subject η -conversion)

- (1) Rule (η -exp) is admissible in $\lambda\cap^\Sigma$ iff Σ is eta.
- (2) Rule (η -red) is admissible in $\lambda\cap_B^\Sigma$ iff Σ validates \mathcal{CDV} , in $\lambda\cap_\Omega^\Sigma$ iff Σ validates \mathcal{BCD} , and it is never admissible in $\lambda\cap_\nu^\Sigma$.

PROOF. (1) (\Rightarrow) Let $\diamond \in \mathbf{C}^\Sigma$ be a constant that does not satisfy the first condition in Definition 9, i.e. $\nu \not\leq_\Sigma \diamond$.

We can derive $x:\diamond \vdash^\Sigma x : \diamond$. To derive $x:\diamond \vdash^\Sigma \lambda y.xy : \diamond$ by Theorem 21(2) we need I, A_i, B_i such that $x:\diamond, y:A_i \vdash^\Sigma xy : B_i$ for all $i \in I$ and $\bigcap_{i \in I} (A_i \rightarrow B_i) \leq_\Sigma \diamond$. Let $I' = \{i \in I \mid B_i \not\sim_\Sigma \Omega\}$. For any $i \in I'$, by Theorem 21(1) we get $x:\diamond, y:A_i \vdash^\Sigma x : D_{i,j} \rightarrow E_{i,j}$, $x:\diamond, y:A_i \vdash^\Sigma y : D_{i,j}$, and $\bigcap_{j \in J_i} E_{i,j} \leq_\Sigma B_i$ for some $J_i, D_{i,j}, E_{i,j}$. By Theorem 22(1) we have $\diamond \leq_\Sigma D_{i,j} \rightarrow E_{i,j}$ and $A_i \leq_\Sigma D_{i,j}$ for all $i \in I'$ and $j \in J_i$. So we conclude

$$\begin{aligned} \bigcap_{i \in I} (A_i \rightarrow B_i) \leq_\Sigma \diamond &\leq_\Sigma \bigcap_{i \in I'} (\bigcap_{j \in J_i} (D_{i,j} \rightarrow E_{i,j})) \\ \forall i \in I'. A_i \leq_\Sigma \bigcap_{j \in J_i} D_{i,j} \ \&\ \bigcap_{j \in J_i} E_{i,j} \leq_\Sigma B_i. \end{aligned}$$

(\Leftarrow) The proof that $\Gamma \vdash^\Sigma M : A$ implies $\Gamma \vdash^\Sigma \lambda x.Mx : A$, where x is fresh, is by induction on the structure of A . The unique non-trivial case is when $A \equiv \psi$ is a type constant not greater than ν . In this case we use the fact that Σ is eta in order to do the derivation discussed in the proof of (\Rightarrow). In details, suppose that $\Gamma \vdash^\Sigma M : \psi$ for some $\psi \in \mathbf{C}^\Sigma$ such that $\nu \not\leq_\Sigma \psi$ and moreover:

$$\begin{aligned} \bigcap_{i \in I} (A_i \rightarrow B_i) \leq_\Sigma \psi &\leq_\Sigma \bigcap_{i \in I'} (\bigcap_{j \in J_i} (D_{i,j} \rightarrow E_{i,j})) \\ \forall i \in I'. A_i \leq_\Sigma \bigcap_{j \in J_i} D_{i,j} \ \&\ \bigcap_{j \in J_i} E_{i,j} \leq_\Sigma B_i, \end{aligned}$$

where $I' = \{i \in I \mid B_i \not\sim_\Sigma \Omega\}$. By rule (\leq), we can derive $\Gamma \vdash^\Sigma M : D_{i,j} \rightarrow E_{i,j}$ for all $i \in I', j \in J_i$, and so $\Gamma, x:D_{i,j} \vdash^\Sigma Mx : E_{i,j}$ by rule (\rightarrow E). From rules (\leq L), (\cap I) and (\leq) we get $\Gamma, x:A_i \vdash^\Sigma Mx : B_i$ for all $i \in I'$. Consider now $i \in I \setminus I'$. In such a case, since $B_i \sim_\Sigma \Omega$, we get immediately, using axiom (Ax- Ω) and rule (\leq), $\Gamma, x:A_i \vdash^\Sigma Mx : B_i$. Therefore, for any $i \in I$, we get $\Gamma \vdash^\Sigma \lambda x.Mx : A_i \rightarrow B_i$ using rule (\rightarrow I). So we can conclude by (\cap I) and (\leq) that $\Gamma \vdash^\Sigma \lambda x.Mx : \psi$.

(2) (\Rightarrow) Let us assume that Σ does not validate axiom (\rightarrow - \cap), i.e. that there are types A, B, C such that $(A \rightarrow B) \cap (A \rightarrow C) \not\leq_\Sigma A \rightarrow B \cap C$. We can derive $x:(A \rightarrow B) \cap (A \rightarrow C) \vdash_B^\Sigma \lambda y.xy : A \rightarrow B \cap C$ using rules (\leq), (\rightarrow E), (\cap I), and (\rightarrow I), but $x : A \rightarrow B \cap C$ cannot be derived from $x:(A \rightarrow B) \cap (A \rightarrow C)$ by Theorem 22(1). Now suppose that Σ does not validate rule (η), i.e. that there are

types A, B, C, D such that $A \leq_{\Sigma} B$ and $C \leq_{\Sigma} D$ but $B \rightarrow C \not\leq_{\Sigma} A \rightarrow D$. We can derive $x:B \rightarrow C \vdash_{\mathcal{B}}^{\Sigma} \lambda y.xy : A \rightarrow D$ using rules (\leq) , $(\rightarrow E)$, and $(\rightarrow I)$, but $x:B \rightarrow C \not\vdash_{\mathcal{B}}^{\Sigma} x : A \rightarrow D$ by Theorem 22(1).

If $\Omega \in \mathbb{C}^{\Sigma}$ we get $x:\Omega \vdash_{\Omega}^{\Sigma} \lambda y.xy : \Omega \rightarrow \Omega$ by axiom (Ax- Ω) and rule $(\rightarrow I)$. By Theorem 22(1) we can derive $x:\Omega \vdash_{\Omega}^{\Sigma} x : \Omega \rightarrow \Omega$ iff $\Omega \leq_{\Sigma} \Omega \rightarrow \Omega$, i.e. iff Σ validates axiom $(\Omega\text{-}\eta)$.

If $\nu \in \mathbb{C}^{\Sigma}$ we get $\vdash_{\nu}^{\Sigma} \lambda y.xy : \nu$ by axiom (Ax- ν), but we cannot derive $x : \nu$ from the empty basis by Theorem 22(1).

(\Leftarrow) We prove that under the given conditions on type preorders $\Gamma \vdash^{\Sigma} \lambda x.Mx : A$ and $x \notin FV(M)$ imply $\Gamma \vdash^{\Sigma} M : A$. We give the proof for $\lambda \cap_{\Omega}^{\Sigma}$, that one for $\lambda \cap_{\mathcal{B}}^{\Sigma}$ being similar and simpler. By Theorem 21(2) $\Gamma \vdash_{\Omega}^{\Sigma} \lambda x.Mx : A$ implies that there are I, B_i, C_i such that $\Gamma, x:B_i \vdash_{\Omega}^{\Sigma} Mx : C_i$ and $\bigcap_{i \in I} (B_i \rightarrow C_i) \leq_{\Sigma} A$. If for some i we get $C_i \sim_{\Sigma} \Omega$, then we can obtain $B_i \rightarrow C_i \sim_{\Sigma} \Omega$ by axiom $(\Omega\text{-}\eta)$ and rule (η) . Therefore we can forget those $B_i \rightarrow C_i$. Otherwise $\Gamma, x:B_i \vdash_{\Omega}^{\Sigma} Mx : C_i$ implies by Theorem 22(2) and rule (S) that $\Gamma \vdash_{\Omega}^{\Sigma} M : D_i \rightarrow C_i$, and $\Gamma, x:B_i \vdash_{\Omega}^{\Sigma} x : D_i$, for some D_i . By Theorem 22(1) we get $B_i \leq_{\Sigma} D_i$, so we can derive $\Gamma \vdash_{\Omega}^{\Sigma} M : B_i \rightarrow C_i$ using rule (\leq) , since $D_i \rightarrow C_i \leq_{\Sigma} B_i \rightarrow C_i$ by rule (η) . Rule $(\cap I)$ implies $\Gamma \vdash_{\Omega}^{\Sigma} M : \bigcap_{i \in I} (B_i \rightarrow C_i)$. So we can conclude $\Gamma \vdash_{\Omega}^{\Sigma} M : A$ using rule (\leq) .

5 Filter λ -structures and Filter Models

In this section we shall see how the results obtained in the previous sections can be used to prove characterisation results concerning domains defined by means of intersection types, the so-called filter λ -structures. In particular, necessary and sufficient conditions will be given that characterize those filter λ -structures that are also models for the (restricted) λ -calculus.

Let us begin with a short discussion about how it is possible to interpret types. There are essentially *two* semantics for intersection types.

One is the *set-theoretical* semantics, originally introduced in [9], generalizing the one given by Scott for simple types. The meanings of types are subsets of the domain of discourse, arrow types are defined as *logical predicates* and intersection is set-theoretic intersection.

The second semantics, which arises in the wake of Stone Duality results (see [1], [12], [32]), views types as *compact elements* of Plotkin's λ -structures [28]. According to this interpretation, the type Ω denotes the least element, intersections denote joins of compact elements, and arrow types allow to internalize the space of continuous endomorphisms. By duality, type preorders give rise to *filter λ -structures*,

where the interpretation of λ -terms can be given through a finitary logical description.

In order to introduce filter λ -structures, let us give the appropriate notion of filter over a type preorder. This is a particular case of filter over a generic \top -meet semi-lattice (see [25]).

Definition 28 (Σ -filters) *Let Σ be a type preorder.*

- (1) A Σ -filter (or a filter over $\mathbb{P}(\mathbb{C}^\Sigma)$) is a set $\Xi \subseteq \mathbb{P}(\mathbb{C}^\Sigma)$ such that
 - (a) if $\Omega \in \mathbb{C}^\Sigma$ then $\Omega \in \Xi$;
 - (b) if $A \leq_\Sigma B$ and $A \in \Xi$, then $B \in \Xi$;
 - (c) if $A, B \in \Xi$, then $A \cap B \in \Xi$.
- (2) \mathcal{F}^Σ the set of Σ -filters over $\mathbb{P}(\mathbb{C}^\Sigma)$.
- (3) If $\Xi \subseteq \mathbb{P}(\mathbb{C}^\Sigma)$, $\uparrow\Xi$ denotes the Σ -filter generated by Ξ .
- (4) A Σ -filter is principal if it is of the shape $\uparrow\{A\}$, for some type A . We shall denote $\uparrow\{A\}$ simply by $\uparrow A$.

It is well known that \mathcal{F}^Σ is an ω -algebraic lattice, whose poset of compact (or finite) elements is isomorphic to the reversed poset obtained by quotienting the preorder on $\mathbb{P}(\mathbb{C}^\Sigma)$ by \sim_Σ . That means that compact elements are the filters of the form $\uparrow A$ for some type A , the top element is $\mathbb{P}(\mathbb{C}^\Sigma)$, and the bottom element is $\uparrow\Omega$ when $\Omega \in \mathbb{C}^\Sigma$ and \emptyset otherwise. Moreover, the join of two filters is the filter induced by their union and the meet of two filters is their intersection, i.e.:

$$\begin{aligned}\Xi \sqcup \Upsilon &= \uparrow(\Xi \cup \Upsilon) \\ \Xi \sqcap \Upsilon &= \Xi \cap \Upsilon.\end{aligned}$$

We now turn the space of filters into an applicative structure.

Definition 29 (Application) *Application $\cdot : \mathcal{F}^\Sigma \times \mathcal{F}^\Sigma \rightarrow \mathcal{F}^\Sigma$ is defined as*

$$\Xi \cdot \Upsilon = \uparrow\{B \mid \exists A \in \Upsilon. A \rightarrow B \in \Xi\}.$$

Taking the Stone duality view-point, the interpretation of terms coincides with the sets of types which are deducible for them:

Definition 30 *For any λ -term M and environment $\rho : Var \rightarrow \mathcal{F}^\Sigma \setminus \{\emptyset\}$,*

$$\llbracket M \rrbracket_\rho^\Sigma = \{A \mid \exists \Gamma \models \rho. \Gamma \vdash^\Sigma M : A\},$$

where Var is the set of term variables and $\Gamma \models \rho$ if and only if $(x : B) \in \Gamma$ implies $B \in \rho(x)$.

We call filter λ -structure the triple $\langle \mathcal{F}^\Sigma, \cdot, \llbracket \cdot \rrbracket^\Sigma \rangle$.

By rules (Ω) , (\leq) and $(\cap I)$, the interpretations of all λ -terms are filters.

Dropping the empty set from the codomain of environments is necessary for obtaining models. First of all, notice that the empty set is a filter only if $\Omega \notin \mathbf{C}^\Sigma$. Clearly, any reasonable interpretation of λ -terms must give the same meaning to the terms z and $(\lambda y.z)x$. If we would allow $\rho(z) = \Xi \neq \emptyset$ and $\rho(x) = \emptyset$ we would get $\llbracket z \rrbracket_\rho^\Sigma = \Xi$ and $\llbracket (\lambda y.z)x \rrbracket_\rho^\Sigma = \emptyset$: in fact no type is derivable for x from a basis which does not contain x when $\Omega \notin \mathbf{C}^\Sigma$. This example is obviously related to the fact that rule $(\text{id}\beta\text{-exp})$ is admissible only when $\Omega \in \mathbf{C}^\Sigma$.

Remark 31 *In the literature (see for instance [16]) filter λ -structures are often referred to as triples $\langle \mathcal{F}^\Sigma, \mathbb{F}^\Sigma, \mathbb{G}^\Sigma \rangle$ where the maps $\mathbb{F}^\Sigma : \mathcal{F}^\Sigma \rightarrow [\mathcal{F}^\Sigma \rightarrow \mathcal{F}^\Sigma]$ and $\mathbb{G}^\Sigma : [\mathcal{F}^\Sigma \rightarrow \mathcal{F}^\Sigma] \rightarrow \mathcal{F}^\Sigma$ are defined by:*

$$\begin{aligned} \mathbb{F}^\Sigma(\Xi) &= \lambda \Upsilon \in \mathcal{F}^\Sigma. \Xi \cdot \Upsilon; \\ \mathbb{G}^\Sigma(f) &= \begin{cases} \uparrow \{A \rightarrow B \mid B \in f(\uparrow A)\} \sqcup \uparrow \nu \text{ if } \nu \in \mathbf{C} \\ \uparrow \{A \rightarrow B \mid B \in f(\uparrow A)\} & \text{otherwise.} \end{cases} \end{aligned}$$

Actually our definition of filter λ -structure coincides with this last one, since application “ \cdot ” allows to recover both \mathbb{F}^Σ and \mathbb{G}^Σ . Moreover, the interpretation $\llbracket \cdot \rrbracket^\Sigma$ coincides with the interpretation of λ -terms induced in the standard way by \mathbb{F}^Σ and \mathbb{G}^Σ . We prefer here the definition of filter λ -structures as triples $\langle \mathcal{F}^\Sigma, \cdot, \llbracket \cdot \rrbracket^\Sigma \rangle$ since it is closer to the syntactic perspective of the previous sections.

The notion of restricted redexes introduced in Definition 23 leads us to consider correspondingly notions of restricted λ -models: first we adapt the classical definition of λ -model à la Hindley-Longo [21] to encompass the various notions of reduction, then we characterise the filter structures which induce these models. To accommodate “call-by-value” λ -calculus we allow the codomains of environments to be proper subsets of the whole domains of models.

Definition 32 (λ -models) *A model for the (restricted) λ -calculus $\lambda_{\mathbf{R}}$ (i.e. of the calculus whose redexes are exactly the \mathbf{R} -redexes) consists of a triple $\langle \mathcal{D}, \cdot, \llbracket \cdot \rrbracket^{\mathcal{D}} \rangle$ such that \mathcal{D} is a set, $\cdot : \mathcal{D} \times \mathcal{D} \rightarrow \mathcal{D}$, $\text{Env} : \text{Var} \rightarrow \mathcal{V}$ for some $\mathcal{V} \subseteq \mathcal{D}$ and the interpretation function $\llbracket \cdot \rrbracket^{\mathcal{D}} : \Lambda \times \text{Env} \rightarrow \mathcal{D}$ satisfies:*

- (1) $\llbracket x \rrbracket_\rho^{\mathcal{D}} = \rho(x)$;
- (2) $\llbracket MN \rrbracket_\rho^{\mathcal{D}} = \llbracket M \rrbracket_\rho^{\mathcal{D}} \cdot \llbracket N \rrbracket_\rho^{\mathcal{D}}$;
- (3) $\llbracket \lambda x.M \rrbracket_\rho^{\mathcal{D}} \cdot \llbracket N \rrbracket_\rho^{\mathcal{D}} = \llbracket M \rrbracket_{\rho[x := \llbracket N \rrbracket_\rho^{\mathcal{D}}]}^{\mathcal{D}}$ for all \mathbf{R} -redexes $(\lambda x.M)N$;
- (4) If $\rho(x) = \rho'(x)$ for all $x \in \text{FV}(M)$, then $\llbracket M \rrbracket_\rho^{\mathcal{D}} = \llbracket M \rrbracket_{\rho'}^{\mathcal{D}}$;
- (5) If $y \notin \text{FV}(M)$, then $\llbracket \lambda x.M \rrbracket_\rho^{\mathcal{D}} = \llbracket \lambda y.M[x := y] \rrbracket_\rho^{\mathcal{D}}$;
- (6) If $\forall d \in \mathcal{D}. \llbracket M \rrbracket_{\rho[x := d]}^{\mathcal{D}} = \llbracket N \rrbracket_{\rho[x := d]}^{\mathcal{D}}$, then $\llbracket \lambda x.M \rrbracket_\rho^{\mathcal{D}} = \llbracket \lambda x.N \rrbracket_\rho^{\mathcal{D}}$.

The restricted model $\langle \mathcal{D}, \cdot, \llbracket \cdot \rrbracket^{\mathcal{D}} \rangle$ is extensional if moreover when $x \notin \text{FV}(M)$:

$$\llbracket \lambda x.Mx \rrbracket_{\rho}^{\mathcal{D}} = \llbracket M \rrbracket_{\rho}^{\mathcal{D}}.$$

Actually, using the Generation Lemmata, we can prove that all filter λ -structures satisfy all the points of the previous definition but the third one.

A direct counterexample to the third point is easy. Considering \mathbf{R} as the set of β -redexes, take for instance the preorder Σ^{\dagger} defined by $\mathbf{C}^{\dagger} = \{\Omega, \varphi\}$, and $\dagger = \{(\dagger)\}$, where

$$(\dagger) \quad \Omega \rightarrow \Omega \sim \Omega \rightarrow \varphi$$

Because of (\dagger) and (\leq) , we have $\vdash_{\Omega}^{\dagger} \lambda x.x : \Omega \rightarrow \varphi$. Let $\rho(y) = \uparrow\Omega$. Then, by $(\rightarrow \text{E})$, we get $\vdash_{\Omega}^{\dagger} (\lambda x.x)y : \varphi$. So

$$\begin{aligned} \llbracket (\lambda x.x)y \rrbracket_{\rho}^{\dagger} &= \{A \mid \exists \Gamma \models \rho. \Gamma \vdash_{\Omega}^{\dagger} (\lambda x.x)y : A\} \text{ by definition of interpretation} \\ &\supseteq \uparrow\varphi && \text{by above} \\ &\neq \uparrow\Omega && \text{since } \varphi \notin \uparrow\Omega \\ &= \llbracket y \rrbracket_{\rho}^{\dagger}. \end{aligned}$$

Lemma 33 For all type preorders Σ the interpretation function $\llbracket \cdot \rrbracket^{\Sigma}$ satisfies conditions (1), (2), (4), (5), (6) of Definition 32.

PROOF. (1) follows immediately from Definition 30 and Theorem 22(1).

(2) Let $A \in \llbracket MN \rrbracket_{\rho}^{\Sigma}$. The case $A \sim_{\Sigma} \Omega$ is trivial. Otherwise there exists a Σ -basis Γ such that $\Gamma \models \rho$ and $\Gamma \vdash^{\Sigma} MN : A$. By Theorem 21(1), there exist I , and $B_i, C_i \in \mathbb{P}(\mathbf{C}^{\Sigma})$ such that $\Gamma \vdash^{\Sigma} M : B_i \rightarrow C_i$, $\Gamma \vdash^{\Sigma} N : B_i$ for all $i \in I$, and $\bigcap_{i \in I} C_i \leq_{\Sigma} A$. Hence $B_i \in \llbracket N \rrbracket_{\rho}^{\Sigma}$ and $B_i \rightarrow C_i \in \llbracket M \rrbracket_{\rho}^{\Sigma}$, for all $i \in I$. By definition of application, it follows $C_i \in \llbracket M \rrbracket_{\rho}^{\Sigma} \cdot \llbracket N \rrbracket_{\rho}^{\Sigma}$ for all $i \in I$, and this implies $A \in \llbracket M \rrbracket_{\rho}^{\Sigma} \cdot \llbracket N \rrbracket_{\rho}^{\Sigma}$, being $\llbracket M \rrbracket_{\rho}^{\Sigma} \cdot \llbracket N \rrbracket_{\rho}^{\Sigma}$ a filter.

Let now $A \in \llbracket M \rrbracket_{\rho}^{\Sigma} \cdot \llbracket N \rrbracket_{\rho}^{\Sigma}$. Then there exist I , and $B_i, C_i \in \mathbb{P}(\mathbf{C}^{\Sigma})$ such that $B_i \rightarrow C_i \in \llbracket M \rrbracket_{\rho}^{\Sigma}$, $B_i \in \llbracket N \rrbracket_{\rho}^{\Sigma}$, for all $i \in I$, and $\bigcap_{i \in I} C_i \leq_{\Sigma} A$. Hence there exist Σ -bases, Γ_i and Γ'_i , such that $\Gamma_i \models \rho$, $\Gamma'_i \models \rho$, and moreover $\Gamma_i \vdash^{\Sigma} M : B_i \rightarrow C_i$, $\Gamma'_i \vdash^{\Sigma} N : B_i$. Consider the Σ -basis $\Gamma'' = \uplus_{i \in I} (\Gamma_i \uplus \Gamma'_i)$. We have $\Gamma'' \models \rho$, $\Gamma'' \vdash^{\Sigma} M : B_i \rightarrow C_i$ and $\Gamma'' \vdash^{\Sigma} N : B_i$. Using rules $(\rightarrow \text{E})$, $(\cap \text{I})$ and (\leq) we deduce $\Gamma'' \vdash^{\Sigma} MN : A$, so we conclude $A \in \llbracket MN \rrbracket_{\rho}^{\Sigma}$.

(4) and (5) are trivial.

(6) Suppose that the premise holds and $A \in \llbracket \lambda x.M \rrbracket_{\rho}^{\Sigma}$. The case $\nu \leq_{\Sigma} A$ is trivial. Otherwise there is a Σ -basis Γ such that $\Gamma \models \rho$ and $\Gamma \vdash^{\Sigma} \lambda x.M : A$. Since $x \notin$

$\text{FV}(\lambda x.M)$, by rule (S) we can assume $x \notin \Gamma$. By Theorem 21(2) there exist I and $B_i, C_i \in \mathbb{T}(\mathbb{C}^\Sigma)$ such that $\Gamma, x : B_i \vdash^\Sigma M : C_i$ for all $i \in I$. Then $C_i \in \llbracket M \rrbracket_{\rho[x := \uparrow B_i]}^\Sigma$: by the premise this implies $C_i \in \llbracket N \rrbracket_{\rho[x := \uparrow B_i]}^\Sigma$, and so $\Gamma_i, x : B_i \vdash^\Sigma N : C_i$ for some Σ -basis Γ_i such that $\Gamma_i \models \rho$. Choosing $\Gamma' = \uplus_{i \in I} \Gamma_i$, we have $\Gamma' \models \rho$ and $\Gamma', x : B_i \vdash^\Sigma N : C_i$ for all $i \in I$. Using rules (\rightarrow I), (\cap I) and (\leq) we deduce $\Gamma' \vdash^\Sigma \lambda x.N : A$, so we conclude $\llbracket \lambda x.M \rrbracket_\rho^\Sigma \subseteq \llbracket \lambda x.N \rrbracket_\rho^\Sigma$. Similarly, one can prove $\llbracket \lambda x.N \rrbracket_\rho^\Sigma \subseteq \llbracket \lambda x.M \rrbracket_\rho^\Sigma$.

Due to the previous lemma, a filter λ -structure is a *model* (i.e. a *filter model*) of the λ -calculus $\lambda_{\mathbf{R}}$ iff the interpretation function $\llbracket \cdot \rrbracket^\Sigma$ equates the \mathbf{R} -redexes with their contracta, that is it satisfies the condition (3) of Definition 32:

$$\llbracket (\lambda x.M)N \rrbracket_\rho^\Sigma = \llbracket M \rrbracket_{\rho[x := \llbracket N \rrbracket_\rho^\Sigma]}^\Sigma \text{ for all } \mathbf{R}\text{-redexes } (\lambda x.M)N.$$

For the successive development it is handy to split the above condition in the following two conditions on type assignment systems which are similar to the rules (R-*exp*) and (R-*red*).

- Definition 34** (1) *Condition (R- $\llbracket \text{exp} \rrbracket$)*: for all x, M, N, Γ, ρ , if $(\lambda x.M)N$ is an \mathbf{R} -redex, $\Gamma \vdash^\Sigma M[x := N] : A$, and $\Gamma \models \rho$, then there is a Σ -basis Γ' such that $\Gamma' \models \rho$ and $\Gamma' \vdash^\Sigma (\lambda x.M)N : A$.
- (2) *Condition (R- $\llbracket \text{red} \rrbracket$)*: for all x, M, N, Γ, ρ , if $(\lambda x.M)N$ is an \mathbf{R} -redex, $\Gamma \vdash^\Sigma (\lambda x.M)N : A$, and $\Gamma \models \rho$, then there is a Σ -basis Γ' such that $\Gamma' \models \rho$ and $\Gamma' \vdash^\Sigma M[x := N] : A$.

Clearly these conditions are more permissive than the corresponding rules: i.e. the admissibility of the rule implies the validity of the condition, but not vice versa.

- Theorem 35** (1) *Condition (var β - $\llbracket \text{exp} \rrbracket$)* holds in all $\lambda\cap^\Sigma$.
- (2) *Condition (fun β - $\llbracket \text{exp} \rrbracket$)* holds in all $\lambda\cap_\Omega^\Sigma$ and $\lambda\cap_\nu^\Sigma$, and in $\lambda\cap_B^\Sigma$ proviso that for all ρ, x, M there are a Σ -basis Γ and a type $A \in \mathbb{T}(\mathbb{C}^\Sigma)$ such that $\Gamma \models \rho$ and $\Gamma \vdash_B^\Sigma \lambda x.M : A$.
- (3) *Condition (id β - $\llbracket \text{exp} \rrbracket$)* holds in all $\lambda\cap_B^\Sigma$ and $\lambda\cap_\Omega^\Sigma$, and in $\lambda\cap_\nu^\Sigma$ proviso that for all ρ, M there are a Σ -basis Γ and a type $A \in \mathbb{T}(\mathbb{C}^\Sigma)$ such that $\Gamma \models \rho$ and $\Gamma \vdash_\nu^\Sigma M : A$.
- (4) *Condition (norm β - $\llbracket \text{exp} \rrbracket$)* holds in all $\lambda\cap^\Sigma$.
- (5) *Condition (β - $\llbracket \text{exp} \rrbracket$)* holds in all $\lambda\cap_\Omega^\Sigma$, and in $\lambda\cap_B^\Sigma$ and $\lambda\cap_\nu^\Sigma$ proviso that for all ρ, M there are a Σ -basis Γ and a type $A \in \mathbb{T}(\mathbb{C}^\Sigma)$ such that $\Gamma \models \rho$ and $\Gamma \vdash^\Sigma M : A$.

PROOF. Admissibility of rule (R-*exp*) implies validity of condition (R- $\llbracket \text{exp} \rrbracket$), hence by Corollary 26 we have that:

- condition ($\text{fun}\beta\text{-}\llbracket\text{exp}\rrbracket$) holds in all $\lambda\cap_{\Omega}^{\Sigma}$ and $\lambda\cap_{\nu}^{\Sigma}$;
- condition ($\text{id}\beta\text{-}\llbracket\text{exp}\rrbracket$) holds in all $\lambda\cap_{\beta}^{\Sigma}$ and $\lambda\cap_{\Omega}^{\Sigma}$;
- condition ($\text{norm}\beta\text{-}\llbracket\text{exp}\rrbracket$) holds in all $\lambda\cap^{\Sigma}$;
- condition ($\beta\text{-}\llbracket\text{exp}\rrbracket$) holds in all $\lambda\cap_{\Omega}^{\Sigma}$.

For the remaining cases, notice that $\Gamma \models \rho$ and $\Gamma' \models \rho$ imply $\Gamma \uplus \Gamma' \models \rho$ by definition of \models . Moreover, if $\Gamma \vdash^{\Sigma} M : A$ we get $\Gamma \uplus \Gamma' \vdash^{\Sigma} M : A$ by rules (\leq L) and (W) for all Γ' . Therefore, by Theorem 24(2), condition ($\mathbf{R}\text{-}\llbracket\text{exp}\rrbracket$) can be rewritten as follows:

for all x, M, N, Γ, ρ , if $(\lambda x.M)N$ is an \mathbf{R} -redex, $\Gamma \vdash^{\Sigma} M[x := N] : A$, and $\Gamma \models \rho$, then there are a Σ -basis Γ' and a type $B \in \mathbb{T}(\mathbb{C}^{\Sigma})$ such that $\Gamma' \models \rho$ and $\Gamma' \vdash^{\Sigma} N : B$.

(1) We get $\{x:B\} \vdash^{\Sigma} x : B$ for all $B \in \rho(x)$: recall that by definition $\rho(x)$ is never empty for all ρ and x .

(2) The condition for $\lambda\cap_{\beta}^{\Sigma}$ is clearly sufficient. It is also necessary: $(\lambda yz.z)(\lambda x.M)$ is a $\text{fun}\beta$ -redex for all x, M and $\vdash_{\beta}^{\Sigma} \lambda z.z : A \rightarrow A$.

(3) The condition for $\lambda\cap_{\nu}^{\Sigma}$ is clearly sufficient. It is also necessary: $(\lambda yz.y)M$ is an $\text{id}\beta$ -redex for all M and $\vdash_{\nu}^{\Sigma} \lambda z.M : \nu$.

(4) The condition for $\lambda\cap_{\beta}^{\Sigma}$ and $\lambda\cap_{\nu}^{\Sigma}$ is clearly sufficient. It is also necessary since $(\lambda yz.z)M$ is a β -redex for all M and $\vdash^{\Sigma} \lambda z.z : A \rightarrow A$.

If $(\lambda x.M)N$ being an \mathbf{R} -redex implies that so is $(\lambda x.M)y$, for a fresh variable y , then condition ($\mathbf{R}\text{-}\llbracket\text{red}\rrbracket$) is equivalent to:

Condition ($\mathbf{R}\text{-}\llbracket\text{red}\rrbracket\text{-*}$): for all x, M, Γ, ρ , if $(\lambda x.M)N$ is an \mathbf{R} -redex for some N , $\Gamma \vdash^{\Sigma} \lambda x.M : B \rightarrow A$, and $\Gamma \models \rho$, then there is a Σ -basis Γ' such that $\Gamma' \models \rho$ and $\Gamma', x:B \vdash^{\Sigma} M : A$.

as proved in the following Theorem.

Theorem 36 *Conditions ($\mathbf{R}\text{-}\llbracket\text{red}\rrbracket$) and ($\mathbf{R}\text{-}\llbracket\text{red}\rrbracket\text{-*}$) are equivalent, proviso $(\lambda x.M)N$ being an \mathbf{R} -redex implies that so is $(\lambda x.M)y$, for a fresh variable y .*

PROOF. (\Rightarrow) Let $(\lambda x.M)N$ be an \mathbf{R} -redex for some N . Assume $\Gamma \vdash^{\Sigma} \lambda x.M : B \rightarrow A$, which implies $\Gamma, y:B \vdash^{\Sigma} (\lambda x.M)y : A$ by rule (\rightarrow E) for a fresh y . Notice that by assumption $(\lambda x.M)y$ is a \mathbf{R} -redex. Notice also that $\Gamma \models \rho$ implies $\Gamma, y:B \models \rho[y := \uparrow B]$. By condition ($\mathbf{R}\text{-}\llbracket\text{red}\rrbracket$) there is $\Gamma' \models \rho[y := \uparrow B]$ such that $\Gamma' \vdash^{\Sigma} M[x := y] : A$. Let $\Gamma'' = \{z:C \in \Gamma' \mid z \neq y\}$: by construction $\Gamma'' \models \rho$ and by rule (\leq L) $\Gamma'', y:B \vdash^{\Sigma} M[x := y] : A$. Hence $\Gamma'', x:B \vdash^{\Sigma} M : A$.

(\Leftarrow) Let $\Gamma \vdash^\Sigma (\lambda x.M)N : A$ and $(\lambda x.M)N$ be an **R**-redex. The case $A \sim_\Sigma \Omega$ is trivial for $\lambda \cap_\Omega^\Sigma$. Otherwise, by Theorem 21(1), there exists a finite set I and types B_i, C_i such that $\Gamma \vdash^\Sigma \lambda x.M : B_i \rightarrow C_i$, $\Gamma \vdash^\Sigma N : B_i$ and $\bigcap_{i \in I} C_i \leq_\Sigma A$. By condition (**R**- $\llbracket red \rrbracket$ -*) there are Γ'_i such that $\Gamma'_i \models \rho$ and $\Gamma'_i, x:B_i \vdash^\Sigma M : C_i$ for all $i \in I$. Let $\Gamma'' = \Gamma \uplus (\biguplus_{i \in I} \Gamma'_i)$: we get $\Gamma'' \models \rho$ by definition of \models . We deduce by (\leq L) and (**W**) $\Gamma'', x:B_i \vdash^\Sigma M : C_i$ and $\Gamma'' \vdash^\Sigma N : B_i$ for all $i \in I$. Then $\Gamma'' \vdash^\Sigma M[x := N] : C_i$ follows by an application of rule (C), and so we can conclude $\Gamma'' \vdash^\Sigma M[x := N] : A$ using rules (\cap I) and (\leq).

Remark that the condition of previous theorem is satisfied when the set of **R**-redexes includes the set of **var** β -redexes.

We end the section by giving the characterisations of the type preorders inducing models of (restricted) λ -calculi. These characterisations, which are generalisations of the corresponding result in [11], follow easily from Theorems 35 and 36.

Theorem 37 (Characterisations of (Restricted) Filter Models) $\langle \mathcal{F}^\Sigma, \cdot, \llbracket \cdot \rrbracket^\Sigma \rangle$ is a model of the

- (1) “call-by-value” λ -calculus iff for all Γ, x, M, A, B, ρ :
 - (a) if $\Gamma \vdash^\Sigma \lambda x.M : A \rightarrow B$ and $\Gamma \models \rho$ then $\Gamma', x : A \vdash^\Sigma M : B$ and $\Gamma' \models \rho$ for some Σ -basis Γ' ;
 - (b) $\llbracket \lambda x.M \rrbracket_\rho^\Sigma \neq \emptyset$;
- (2) $\lambda\mathbf{I}$ -calculus iff for all Γ, x, M, A, B, ρ such that $x \in FV(M)$:
 - (a) if $\Gamma \vdash^\Sigma \lambda x.M : A \rightarrow B$ and $\Gamma \models \rho$ then $\Gamma', x : A \vdash^\Sigma M : B$ and $\Gamma' \models \rho$ for some Σ -basis Γ' ;
 - (b) if $\nu \in \mathbf{C}^\Sigma$ then $\llbracket M \rrbracket_\rho^\Sigma \neq \emptyset$;
- (3) $\lambda\mathbf{KN}$ -calculus iff for all Γ, x, M, A, B, ρ :
 - (a) if $\Gamma \vdash^\Sigma \lambda x.M : A \rightarrow B$ and $\Gamma \models \rho$ then $\Gamma', x : A \vdash^\Sigma M : B$ and $\Gamma' \models \rho$ for some Σ -basis Γ' ;
 - (b) if $\nu \in \mathbf{C}^\Sigma$ then $\llbracket M \rrbracket_\rho^\Sigma \neq \emptyset$;
- (4) whole λ -calculus iff for all Γ, x, M, A, B, ρ :
 - (a) if $\Gamma \vdash^\Sigma \lambda x.M : A \rightarrow B$ and $\Gamma \models \rho$ then $\Gamma', x : A \vdash^\Sigma M : B$ and $\Gamma' \models \rho$ for some Σ -basis Γ' ;
 - (b) $\llbracket M \rrbracket_\rho^\Sigma \neq \emptyset$.

PROOF. First of all notice that all considered calculi satisfy the condition of Theorem 36. More precisely in all these calculi but in the $\lambda\mathbf{I}$ -calculus the set of redexes includes the set of **var** β -redexes. Instead for all variables y we have that $(\lambda x.M)y$ is a $\beta\mathbf{I}$ -redex whenever $(\lambda x.M)N$ is a $\beta\mathbf{I}$ -redex.

Condition (a) specialises condition (**R**- $\llbracket red \rrbracket$ -*) for the considered restrictions of

λ -calculus, and therefore by Theorem 36, (a) is necessary and sufficient to assure:

$$\llbracket (\lambda x.M)N \rrbracket_{\rho}^{\Sigma} \subseteq \llbracket M \rrbracket_{\rho[x:=\llbracket N \rrbracket_{\rho}^{\Sigma}]}^{\Sigma}.$$

Taking into account that $\llbracket M \rrbracket_{\rho}^{\Sigma} \neq \emptyset$ iff there are $\Gamma \models \rho, A$ such that $\Gamma \vdash^{\Sigma} M : A$, Theorem 35 implies that condition (b) is necessary and sufficient to assure:

$$\llbracket M \rrbracket_{\rho[x:=\llbracket N \rrbracket_{\rho}^{\Sigma}]}^{\Sigma} \subseteq \llbracket (\lambda x.M)N \rrbracket_{\rho}^{\Sigma}.$$

As an immediate consequence of Theorem 37(4) and Theorem 22(3), $\langle \mathcal{F}^{\Sigma}, \cdot, \llbracket \cdot \rrbracket^{\Sigma} \rangle$ is a λ -model whenever Σ is a beta theory and $\Omega \in \mathbb{C}^{\Sigma}$.

We can also characterise filter models which are extensional using Theorem 27. Note that for the η -rule the possibility of changing basis (in agreement with a fixed environment) plays a role only if $\nu \in \mathbb{C}$, since in all other cases the sub-formula property holds and η -convertible terms have the same set of free variables.

Theorem 38 (Characterisation of extensional (restricted) filter models) *Let Σ be a type preorder. The filter λ -structure $\langle \mathcal{F}^{\Sigma}, \cdot, \llbracket \cdot \rrbracket^{\Sigma} \rangle$ is an extensional filter model of the restricted λ -calculus $\lambda_{\mathbb{R}}$ iff it is a model of $\lambda_{\mathbb{R}}$, Σ is an eta type preorder which validates CDV , and moreover if $\Omega \in \mathbb{C}^{\Sigma}$ then Σ validates axiom $(\Omega-\eta)$, if $\nu \in \mathbb{C}^{\Sigma}$ then $\nu \in \llbracket M \rrbracket_{\rho}^{\Sigma}$ for all M, ρ .*

PROOF. (\Rightarrow) Let $\varphi \in \mathbb{C}^{\Sigma}$ be a constant that satisfies neither conditions of Definition 9. One can show that $\varphi \notin \llbracket \lambda y.xy \rrbracket_{\rho[x:=\uparrow\varphi]}^{\Sigma}$: this implies that Σ must be eta.

We have $A \rightarrow B \cap C \in \llbracket \lambda y.xy \rrbracket_{\rho[x:=\uparrow(A \rightarrow B) \cap (A \rightarrow C)]}^{\Sigma}$ for all A, B, C , but $A \rightarrow B \cap C \in \uparrow(A \rightarrow B) \cap (A \rightarrow C)$ only if Σ validates axiom $(\rightarrow-\cap)$. Similarly, one can show that Σ must validate axiom (η) always, and axiom $(\Omega-\eta)$ when $\Omega \in \mathbb{C}^{\Sigma}$. Lastly if $\nu \in \mathbb{C}^{\Sigma}$ then $\nu \in \llbracket \lambda x.Mx \rrbracket_{\rho}^{\Sigma}$ for all M, ρ by axiom $(Ax-\nu)$: therefore we need $\nu \in \llbracket M \rrbracket_{\rho}^{\Sigma}$ for all M, ρ .

(\Leftarrow) follows from Theorem 27, but for the case $\nu \in \mathbb{C}^{\Sigma}$, in which ν is harmless being contained in the interpretations of all terms.

Using Proposition 7(1), Lemma 21 and previous theorems we get:

- $\langle \mathcal{F}^{\nabla}, \cdot, \llbracket \cdot \rrbracket^{\nabla} \rangle$ with $\nabla \in \{Ba, CDV\}$ is a model of the $\lambda\mathbf{I}$ -calculus,
- $\langle \mathcal{F}^{\nabla}, \cdot, \llbracket \cdot \rrbracket^{\nabla} \rangle$ with $\nabla \in \{\mathcal{HL}, \mathcal{HR}\}$ is an extensional model of the $\lambda\mathbf{I}$ -calculus,
- $\langle \mathcal{F}^{\mathcal{EHR}}, \cdot, \llbracket \cdot \rrbracket^{\mathcal{EHR}} \rangle$ is a model of the “call-by-value” λ -calculus,
- $\langle \mathcal{F}^{\nabla}, \cdot, \llbracket \cdot \rrbracket^{\nabla} \rangle$ with $\nabla \in \{\mathcal{AO}, BCD, Pl, \mathcal{E}n\}$ is a model of the whole λ -calculus,
- $\langle \mathcal{F}^{\nabla}, \cdot, \llbracket \cdot \rrbracket^{\nabla} \rangle$ with $\nabla \in \{\mathcal{Sc}, Pa, CDZ, \mathcal{DHM}\}$ is an extensional model of the whole λ -calculus.

Let Σ^\diamond be the preorder defined in example 8: [4] proves that it induces a model of the whole λ -calculus by showing condition (4)(a) of Theorem 37.

6 Conclusion

When stepping into the world of λ -calculus semantics, intersection type systems turn out to be a useful “vehicle” to move around, since they provide a finitary way to describe and analyse particular classes of models. By simply adding a single constant or condition on a type preorder, a different semantical domain is characterized. One is then naturally induced to expect that intersection types will provide, in the long run, a sort of tailor shop in which particular domains can be tailored for any specific need.

In the present paper we have provided characterisation results concerning intersection type systems for the λ -calculus, for a number of its restrictions and for their corresponding extensional versions. Some results characterise those intersection type systems for which typing invariance holds w.r.t. β - and η -conversion. Filter λ -structures induced by intersection type preorders have been shown to provide models for the whole λ -calculus and for a number of relevant “restricted” λ -calculi whenever particular conditions on the type preorders are fulfilled. These characterisations have an interest *per se* in the syntactic theory of intersection types. However, the paper keeps also a general perspective, since expansion/reduction results are parametric over the set of restricted redexes. Therefore we have a basis for further analysis: whenever operational investigation will point at new sets of restricted redexes, the present paper’s results will provide a useful preliminary tool for isolating conversion properties, thus characterising the corresponding filter models.

Acknowledgements The authors are grateful to Furio Honsell, Henk Barendregt and Wil Dekkers for enlightening discussions on the subject of the present paper. Moreover, they would like to thank the two anonymous referees for their several suggestions about the form of the paper as well as their help in correcting a few flaws in some proofs. The authors thank also the referees of WoLLIC’03 and TYPES’03 for careful reading preliminary versions of this paper and for their useful comments. The second author wishes to express his thanks to Gisella Meli and Alessandro Cavalli.
